

# The two-phase Stefan problem: regularization near Lipschitz initial data by phase dynamics.

Sunhi Choi\*and Inwon Kim†

## Abstract

In this paper we investigate the regularizing behavior of two-phase Stefan problem near initial Lipschitz data. A description of the regularizing phenomena is given in terms of the corresponding space-time scale.

## 1 Introduction

Consider  $u_0(x) : B_R(0) \rightarrow \mathbb{R}$  with  $R \gg 1$  and  $u_0 \geq -1$ ,  $|\{u_0 = 0\}| = 0$  and  $u_0(x) = -1$  on  $\partial B_R(0)$ . (See Figure 1.) The two-phase Stefan problem can be formally written as

$$(ST2) \quad \begin{cases} u_t - \Delta u = 0 & \text{in } \{u > 0\} \cup \{u < 0\} \\ \frac{u_t}{|Du^+|} = |Du^+| - |Du^-| & \text{on } \partial\{u > 0\} \\ u(\cdot, 0) = u_0 \\ u = -1 & \text{on } \partial B_R(0) \end{cases}$$

Here  $Du$  denotes the spatial derivative of  $u$ .  $u^+$  and  $u^-$  respectively denote the positive and negative parts of  $u$ , i.e.,

$$u^+ := \max(u, 0) \text{ and } u^- := -\min(u, 0).$$

The classical Stefan problem describes the phase transition between solid/liquid or liquid/liquid interface (see [M] and also [OPR].) In our setting, we consider a bounded domain  $\Omega_0 \subset B_R(0)$  and the initial data  $u_0(x)$  such that

$$\{u_0 > 0\} = \Omega_0 \text{ and } \{u_0 < 0\} = B_R(0) - \overline{\Omega_0}.$$

To avoid complications at the infinity, we consider the problem in the domain  $Q = B_R(0) \times [0, \infty)$ , with Dirichlet condition

$$u = f(x, t) < 0 \text{ on } \partial B_R(0),$$

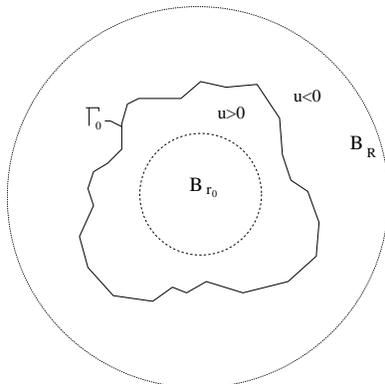

Figure 1: Initial setting of the problem

where  $f(x, t)$  is smooth. In (ST2) we have set  $f = -1$  for simplicity. Since our initial data will be only locally Hölder continuous, we employ the notion of viscosity solutions to discuss the evolution of the problem. Viscosity solutions for (ST2) is originally introduced by [ACS1] (also see [CS]). As for existence and uniqueness of viscosity solutions, we refer to [KP].

Note that the second condition of (ST2) states that the normal velocity  $V_{x,t}$  at each free boundary point  $(x, t) \in \partial\{u > 0\}$  is given by

$$V_{x,t} = (|Du^+| - |Du^-|)(x, t) = (Du^+(x, t) - Du^-(x, t)) \cdot \nu_{x,t},$$

where  $\nu_{x,t}$  denotes the spatial unit normal vector of  $\partial\{u > 0\}$  at  $(x, t)$ , pointing inward with respect to the *positive phase*  $\{u > 0\}$ .

In this paper we investigate the regularizing behavior of the *free boundary*  $\partial\{u > 0\}$ . Our main result states that when  $\Gamma_0$  is locally a Lipschitz graph with small Lipschitz constant, then the free boundary immediately regularizes and becomes smooth after  $t = 0$ . Moreover we provide a natural space-time scale for such regularization. More precisely, for  $x_0 \in \partial\{u_0 > 0\}$ , we show that the free boundary regularizes in  $B_d(x_0)$  by the time  $t(x_0, d)$  given in (1.3) (see Theorem 1.1, and also the heuristic discussion below (1.3)). Corresponding results have been obtained in recent studies on the one-phase free boundary problems ([CJK1], [CJK2], [CK]), but the presence of two phases poses new challenges in the analysis. For example there is no generic class of global solutions other than radial solutions where topological changes are ruled out. In the one-phase setting we handily used the fact that solutions with star-shaped initial data stay star-shaped over time: this is no longer true in the two-phase setting (see Remark 3.1). More importantly, the interface motion is no longer monotone and the competition between positive and negative fluxes across the free boundary necessitates additional localization procedure (see the remarks below Theorem 1.1).

The celebrated results of [ACS1]-[ACS2] state that if the solution of (ST2) stays close to a Lipschitz profile in the unit space-time neighborhood  $B_1(0) \times [0, 1]$ , then the solution is indeed smooth in half of the neighborhood  $B_{1/2}(0) \times [1/2, 1]$ . The main step in our analysis is to prove that the free boundary  $\partial\{u > 0\}$  stays close to a locally Lipschitz profile in any given scale. Proving this step corresponds to derivation of several Harnack-type inequalities for our problem, which are of independent interest.

Before discussing our result in detail, let us introduce precise conditions on the initial data.

(I-a)  $\Omega_0$  and  $u_0$  are star-shaped with respect to a ball  $B_{r_0}(0) \subset \Omega_0$ .

Observe that then the *Lipschitz constant*  $L$  of  $\partial\Omega_0$  is determined by  $r_0$  and  $d_0$ , where

$$d_0 := \sup\{d(x, B_{r_0}(0)) : x \in \partial\Omega_0\}.$$

In other words, there exist  $h = h(r_0)$  and  $L = L(r_0, d_0)$  such that for any  $x_0 \in \partial\Omega_0$ , after rotation of coordinates one may represent

$$B_h(x_0) \cap \Omega_0 = \{(x', x_n) : x' \in \mathbb{R}^{n-1}, x_n \leq f(x')\} \text{ with } Lip f \leq L. \quad (1.1)$$

For simplicity of the presentation we set  $h = 1$ .

For a locally Lipschitz domain such as  $\Omega_0$ , there exist growth rates  $0 < \beta < 1 < \alpha$  such that the following holds: let  $H$  be a positive harmonic function in  $\Omega_0 \cap B_2(x)$ ,  $x \in \partial\Omega_0$ , with Dirichlet condition on  $\partial\Omega_0 \cap B_2(x)$ , and with value 1 at  $x - e_n$ . (Here let  $e_n$  be the direction of the axis for the Lipschitz graph near  $x$ .) Then for  $x - se_n \in \Omega_0 \cap B_1(x)$

$$s^\alpha \leq H(x - se_n) \leq s^\beta. \quad (1.2)$$

Below we list conditions on the range of the Lipschitz constant  $L$  of the initial positive phase  $\Omega_0$ .

(I-b)  $L < L_n$  for a sufficiently small dimensional constant  $L_n$  so that

$$5/6 \leq \beta < \alpha \leq 7/6.$$

The remaining conditions are on the regularity of  $u_0$ .

(I-c)  $-N_0 \leq \Delta u_0 \leq N_0$  in  $\Omega_0 \cup (B_R(0) - \overline{\Omega_0})$ ,

(I-d) For  $x \in \partial\Omega_0$ , we may let  $e_n = x/|x|$  after a rotation. Then for small  $s > 0$  (for  $0 < s < 1/10$ ),

$$|Du_0(x \pm se_n)| \geq Cs^{\alpha-1}.$$

Note that (I-c) and (I-d) hold for  $u_0$  which is smooth in its positive and negative phases and is harmonic near the initial free boundary: i.e.,  $-\Delta u_0 = 0$  in the set  $(\{u_0 > 0\} \cup \{u_0 < 0\}) \cap \{x : d(x, \partial\Omega_0) \leq 1\}$ .

For a function  $u(x, t) : \mathbb{R}^n \times [0, \infty) \rightarrow \mathbb{R}$ , let us denote

$$\Omega(u) := \{u > 0\}, \quad \Omega_t(u) := \{u(\cdot, t) > 0\}$$

and

$$\Gamma(u) := \partial\{u > 0\}, \quad \Gamma_t(u) := \partial\{u(\cdot, t) > 0\}.$$

Since  $\Gamma_0 = \partial\{u(\cdot, 0) > 0\} = \partial\{u(\cdot, 0) < 0\}$  in our setting, the property is preserved for later times, i.e.,

$$\Gamma_t(u) = \partial\{u(\cdot, t) > 0\} = \partial\{u(\cdot, t) < 0\} \text{ for all } t > 0$$

(see [RB], [GZ], and [KP]).

• For  $x_0 \in \Gamma_0 = \Gamma_0(u)$ , we may let  $e_n = x_0/|x_0|$  after a rotation. Then we define

$$R^+(x_0, r) := \frac{u^+(x_0 - re_n, 0)}{u^-(x_0 + re_n, 0)}, \quad R^-(x_0, r) := \frac{u^-(x_0 + re_n, 0)}{u^+(x_0 - re_n, 0)}$$

and

$$t(x_0, r) := \min\left[\frac{r^2}{u^+(x_0 - re_n, 0)}, \frac{r^2}{u^-(x_0 + re_n, 0)}\right]. \quad (1.3)$$

Some remark concerning  $t(x_0, r)$  is in order. In one-phase case (where  $u^- \equiv 0$ ), it was shown in [CJK1] that

$$t(x_0, r) \sim \sup\{t > 0 : u(x_0 + re_n, t) = 0\},$$

i.e.  $t(x_0, r)$  is the time it takes for the free boundary to reach  $x_0 + re_n$ . In our (two-phase) case  $t(x_0, r)$  is the time it takes for the free boundary to reach  $x_0 + re_n$  if we evolved the free boundary only according to the dominant phase with bigger size of  $u$ . In particular  $\Gamma(u)$  moves at most by distance  $r$  by the time  $t(x_0, r)$ . It turns out that  $t(x_0, r)$  is the correct time scale for the solutions in  $r$ -neighborhood of  $x_0$  to “mix” and regularize the interface (Theorem 1.1 (3)). See the paragraph below Theorem 1.1 for further heuristics based on scaling properties of our problem.

**Theorem 1.1** (Main Theorem I: Theorem 5.6, Theorem 5.7 and Corollary 5.8). *Suppose  $u$  is a solution of (ST2) with initial data  $u_0$  satisfying (Ia)-(Id) with  $\Omega_0(u) \subset B_R(0)$ . Due to (Ia)-(Ib), , for sufficiently small  $r$  and given  $x_0 \in \Gamma_0$  the initial free boundary  $\Gamma_0$  is given by the graph of a Lipschitz function in  $B_r(x_0)$ . After a rotation if necessary, we may assume that*

$$\Omega_0 \cap B_r(x_0) = \{x + x_0 : x = (x', x_n), x_n \leq f(x')\}$$

where  $f$  is a Lipschitz function with Lipschitz constant  $L < L_n$ . Then the following conclusions hold for  $u$ .

With above setting, there exists  $d_0 > 0$  depending only on  $n$  and  $N_0$  such that the following holds for  $r \leq d_0$ :

(1) In  $\Sigma_r := B_{2r}(x_0) \times [t(x_0, r)/2, t(x_0, r)]$ , we have

$$\Gamma(u) = \{x + x_0 : x = (x', x_n), x_n \leq f(x', t)\},$$

where  $f(x', t)$  is a  $C^1$  function in space and time. Moreover, there exists a positive dimensional constant  $c_0$  and  $1 < m < 2$  such that

$$|D_{x'} f(x', t) - D_{x'} f(y', t)| \leq c_0 (-\log |\frac{x'}{r} - \frac{y'}{r}|)^{-m},$$

$$|\partial_t f(x', t) - \partial_t f(x', s)| \leq c_0 (-\log |\frac{t}{t(x_0, r)} - \frac{s}{t(x_0, r)}|)^{-1/3}.$$

(2)  $u$  is a classical solution of (ST2) in  $\Sigma_r$  in the sense that

- (i)  $Du^+$  exists in  $\Omega(u)$  and is continuous up to  $\bar{\Omega}(u)$ ;
- (ii)  $Du^-$  exists in  $\Omega(u)$  and is continuous up to  $\Sigma_r \cap (\mathbb{R}^n - \Omega(u))$ ;
- (iii) the free boundary condition is satisfied in the classical sense, i.e.,

$$V_{x,t} = (|Du^+| - |Du^-|)(x, t) \text{ on } \Gamma(u) \cap \Sigma_r.$$

(3) There exists a positive dimensional constant  $M$  such that

$$M^{-1} \frac{u^+(x_0 - re_n, 0)}{r} \leq |Du^+|(x, t) \leq M \frac{u^+(x_0 - re_n, 0)}{r}$$

and

$$M^{-1} \frac{u^-(x_0 + re_n, 0)}{r} \leq |Du^-|(x, t) \leq M \frac{u^-(x_0 + re_n, 0)}{r}$$

in  $\Sigma_r$ .

**Remark 1.2.** Our result extends to the case where the star-shaped condition (I-a)-(I-b) is replaced by

(I-ab)  $\Omega_0$  is locally Lipschitz with a sufficiently small Lipschitz constant.

We will discuss in section 6 the differences in the proof in this case.

The one phase version of above result has been proved in [CK] (see Theorem 2.16 in section 2). Let us briefly motivate our result below.

For a given reference point  $(x_0, t_0) \in \mathbb{R}^n \times [0, \infty)$  and positive constants  $r$  and  $c$ , one can re-scale the solution  $u$  of (ST2) as follows:

$$\tilde{u} := \frac{1}{c} u(x_0 + rx, t_0 + \frac{r^2}{c} t). \quad (1.4)$$

Then  $\tilde{u}$  satisfies the following free boundary problem

$$(\tilde{P}) \quad \begin{cases} r\tilde{u}_t - \Delta \tilde{u} = 0 & \text{in } \{\tilde{u} > 0\} \cup \{\tilde{u} < 0\}; \\ V = |D\tilde{u}^+| - |D\tilde{u}^-| & \text{on } \partial\{\tilde{u} > 0\} \end{cases}$$

in a corresponding neighborhood of the origin. Let  $e_1, \dots, e_n$  be the orthonormal basis of  $\mathbb{R}^n$  so that  $x \in \mathbb{R}^n$  can be denoted as  $x = (x', x_n)$ ,  $x_n = x \cdot e_n$ . Now choose  $(x_0, t_0) = (x_0, 0)$  with  $x_0 \in \Gamma_0(u)$ . By our hypothesis, after a change of coordinates if necessary, there exists a Lipschitz function  $f : \mathbb{R}^{n-1} \rightarrow \mathbb{R}$  with a small Lipschitz constant such that

$$\Omega_0(u) \cap B_{2r}(x_0) = \{x : x_n \leq f(x')\}.$$

Let us choose

$$c = \max\{u^+(x_0 - re_n, 0), u^-(x_0 + re_n, 0)\} \quad (1.5)$$

so that one of  $\tilde{u}^+(-e_n, 0)$  and  $\tilde{u}^+(+e_n, 0)$  equals 1, and the other is less than 1.

Now suppose that we can show the following two conditions (A) and (B):

(A)  $|\tilde{u}|(x, t) \leq C$  in  $B_1(0) \times [0, 1]$  with a constant  $C > 0$  independent of  $x_0$  and  $r$ ;

(B) The level sets of  $\tilde{u}$  are Lipschitz graphs in space and time with small Lipschitz constant in  $B_1(0) \times [0, 1]$ .

Then Theorem 1.1 follows from the results of [ACS1] applied to  $\tilde{u}$ . Indeed, (B) can be replaced by a relaxed version (B') as stated below, which is sufficient to derive Theorem 1.1 due to the results of [ACS2].

(B') The level sets of  $\tilde{u}$  are  $\epsilon$ -monotone with respect to cones of directions  $W_x(\theta^x, e)$  and  $W_t(\theta^t, \nu)$  with  $\nu \in \text{span}(e_n, e_t)$ , and  $\pi/2 - \theta^x$  and  $\epsilon$  sufficiently small.

(For the definition of  $\epsilon$ -monotonicity and the space and time cones  $W_x$  and  $W_t$ , see Definition 2.1 below.)

In our case (A) can be verified using the one-phase results (see section 2). Unfortunately, as shown in [CK], verifying (B') for all scales  $r$  turns out to be as difficult as showing (B) or the full regularity of  $u$ . Since  $\tilde{u}$  no longer satisfies the heat equation, one loses control of the change of  $u$  over time. In particular for this reason it is necessary to show (B') for all level sets of  $\tilde{u}$ , not just for the free boundary  $\Gamma(\tilde{u})$ . Indeed in this article we will first show that  $\tilde{u}$  (scaled correspondingly for the two-phase) is  $\epsilon$ -monotone in space variable (section 3), and then we show that  $\Gamma(\tilde{u})$  is  $\epsilon$ -monotone in space-time variables (section 4). We use this fact, the almost-harmonicity of  $\tilde{u}$ , as well as the iteration methods originated from [ACS1]-[ACS2] to show directly that  $\tilde{u}$  is a classical solution and  $u$  satisfies (B) and (B') (section 5). The arguments in the last section are mostly drawn from [ACS1]-[ACS2] as well as [CJK1]-[CJK2].

In terms of the original solution  $u$ , verifying (A) – (B') corresponds to analyzing  $u$  over the time interval  $[0, t(x_0, r)]$ , where  $t(x_0, r)$  is given by

$$t(x_0, r) := \frac{r^2}{c}.$$

where  $c$  is as given in (1.5). Note that  $t(x_0, r)$  coincides with the one given by (1.3).

Heuristically speaking, there are two possible scenarios for interface regularization, depending on its initial configuration in the local neighborhood:

- (1) One of the phases has much bigger flux than the other, i.e.,

$$u^+(x_0 - se_n, 0) \gg u^-(x_0 + se_n, 0) \text{ or } u^-(x_0 - se_n, 0) \ll u^-(x_0 + se_n, 0)$$

for  $s$  comparable to  $r$ .

In this case one-phase like phenomena (regularization by the dominant phase as obtained in Theorem 2.16) is expected. As mentioned above, in this case the time interval for regularization of the free boundary in  $r$ -neighborhood is proportional to the distance it has travelled.

- (2) Both phases are in balance, i.e.

$$u^+(x_0 - se_n, 0) \sim u^-(x_0 + se_n, 0) \tag{1.6}$$

for  $s$  comparable to  $r$ .

In this case one expects regularization due to competition between two phases, resulting in Lipschitz-like behavior over time. Again the corresponding time interval for regularization amounts to  $t(x_0, r)$  given in (1.3).

To make above heuristics rigorous, we will introduce a decomposition procedure based on Harnack-type inequalities, which illustrates local dynamics near the free boundary: roughly speaking, for given  $r > 0$  we divide  $B_r(x_0) \times \{t = 0\}$  into regions where (1.6) holds for  $0 < s \ll r$  (*balanced* region) and the rest of domain (*unbalanced* region). (See detailed definitions of these regions in section 4.) Of course the main issue is whether the dynamics of one region affects the other, in particular whether the one-phase type dynamics of the unbalanced region breaks the property (1.6) in the balanced region for future times. We will show that this does not happen due to fast regularization property in the unbalanced region as well as Harnack-type inequalities in the balanced region. (See Proposition 4.3 in section 4.)

Let us finish this section with an outline of the paper. In section 2 we introduce preliminary results and notations. Sections 3 to 5 consist of the proof of Theorem 1.1. In section 3 we prove some properties on the evolution of solutions of (ST2) with star-shaped data. In addition to Harnack inequalities, we show that the solution stays near the star-shaped profile for a unit time (Lemma 3.1), which in turn yields that the solution stays very close to harmonic functions (Lemma 3.6). This establishes that (B') holds in space variable. Making use of the results in section 3, we perform a decomposition procedure, in section 4, to show that (A) holds for  $\tilde{u}$  and that (B') holds for  $\Gamma(\tilde{u})$ . This completes our

main step in the analysis. In section 5 we describe the rather technical iteration procedure leading to further regularization, and we complete the proof of Theorem 1.1 by combining arguments from previous arguments in [ACS1], [ACS2], [CJK1]-[CJK2]. In section 6 we discuss a generalized proof of the corresponding regularization result (Theorem 6.1) when the star-shapedness of the initial data (I-a) and (I-b) are replaced by a local version (I-ab).

## 2 Preliminary lemmas and notations

We introduce some notations.

- For  $x \in \mathbb{R}^n$ , denote  $x = (x', x_n) \in \mathbb{R}^{n-1} \times \mathbb{R}$  where  $x_n = x \cdot e_n$ .
- Let  $B_r(x)$  be the space ball of radius  $r$ , centered at  $x$ .
- Let  $Q_r := B_r(0) \times [-r^2, r^2]$  be the parabolic cube and let  $K_r := B_r(0) \times [-r, r]$  be the hyperbolic cube.
- A caloric function in  $\Omega \cap Q_r$  will denote a nonnegative solution of the heat equation, vanishing along the lateral boundary of  $\Omega$ .
- For  $x_0 \in \Gamma_0$  and  $e_n = x_0/|x_0|$ , define

$$t(x_0, d) := \min\left[\frac{d^2}{u^+(x_0 - de_n, 0)}, \frac{d^2}{u^-(x_0 + de_n, 0)}\right].$$

- $C$  is called an universal constant if it depends only on the dimension  $n$  and the regularity constant  $N_0$  of  $u_0$ .
- We say  $a \sim b$  if there exists a universal constant  $C > 0$  such that  $C^{-1}b \leq a \leq Cb$ .

Lastly let us recall the definition of  $\epsilon$ -monotonicity.

- Let  $W_x(\theta^x, e)$  and  $W_t(\theta^t, \nu)$  with  $e \in \mathbb{R}^n$  and  $\nu \in \text{span}(e_n, e_t)$  respectively denote a spatial circular cone of aperture  $2\theta^x$  and axis in the direction of  $e$ , and a two-dimensional space-time cone in  $(e_n, e_t)$  plane of aperture  $2\theta^t$  and axis in the direction of  $\nu$ .

**Definition 2.1.** (a) Given  $\epsilon > 0$ , a function  $w$  is called  $\epsilon$ -monotone in the direction  $\tau$  if

$$u(p + \lambda\tau) \geq u(p) \text{ for any } \lambda \geq \epsilon.$$

- (b)  $w$  is  $\epsilon$ -monotone in a cone of directions  $W_x(\theta^x, e)$  or  $W_t(\theta^t, \nu)$  if  $w$  is  $\epsilon$ -monotone in every direction in the cone.

Next we state preliminary results that are important in our analysis. The first lemma is a direct consequence of the interior Harnack inequalities proved in [C-C].

**Lemma 2.2** ([C-C]). *Suppose  $w(x) : \mathbb{R}^n \rightarrow \mathbb{R}$  has bounded Laplacian. Then  $w$  is Hölder continuous with its constant depending on the Laplacian bound.*

**Lemma 2.3** ([FGS1], Theorem 3). *Let  $\Omega$  be a domain in  $\mathbb{R}^n \times \mathbb{R}$  such that  $(0, 0)$  is on its lateral boundary. Suppose  $\Omega$  is a  $Lip^{1,1/2}$  domain, i.e.,*

$$\Omega = \{(x', x_n, t) : |x'| < 1, |x_n| < 2L, |t| < 1, x_n \leq f(x', t)\},$$

where  $f$  satisfies  $|f(x', t) - f(y', s)| \leq L(|x' - y'| + |t - s|^{1/2})$ . If  $u$  is a caloric function in  $\Omega$ , then there exists  $C = C(n, L)$ , where  $L$  is the Lipschitz constant for  $\Omega$ , such that

$$\frac{u(x, t)}{v(x, t)} \leq C \frac{u(-Le_n, 1/2)}{v(-Le_n, -1/2)}.$$

for  $(x, t) \in Q_{1/2}$ .

**Lemma 2.4** ([ACS1], Theorem 1). *Let  $\Omega$  be a Lipschitz domain in  $\mathbb{R}^n \times \mathbb{R}$ , i.e.,*

$$Q_1 \cap \Omega = Q_1 \cap \{(x, t) : x_n \leq f(x', t)\},$$

where  $f$  satisfies  $|f(x, t) - f(y, s)| \leq L(|x - y| + |t - s|)$ . Let  $u$  be a caloric function in  $Q_1 \cap \Omega$  with  $(0, 0) \in \partial\Omega$  and  $u(-e_n, 0) = m > 0$  and  $\sup_{Q_1} u = M$ . Then there exists a constant  $C$ , depending only on  $n, L, \frac{m}{M}$  such that

$$u(x, t + \rho^2) \leq Cu(x, t - \rho^2)$$

for all  $(x, t) \in Q_{1/2} \cap \Omega$  and for  $0 \leq \rho \leq d_{x,t}$ .

**Lemma 2.5** ([ACS1], Lemma 5). *Let  $u$  and  $\Omega$  be as in Lemma 2.4. Then there exist  $a, \delta > 0$  depending only on  $n, L, \frac{m}{M}$  such that*

$$w_+ := u + u^{1+a} \text{ and } w_- := u - u^{1+a}$$

are subharmonic and superharmonic, respectively, in  $Q_\delta \cap \Omega \cap \{t = 0\}$ .

Next we state several properties of harmonic functions:

**Lemma 2.6** ([D]). *Let  $u_1, u_2$  be two nonnegative harmonic functions in a domain  $D$  of  $\mathbb{R}^n$  of the form*

$$D = \{(x', x_n) \in \mathbb{R}^{n-1} \times \mathbb{R} : |x'| < 2, |x_n| < 2L, x_n > f(x')\}$$

with  $f$  a Lipschitz function with constant less than  $L$  and  $f(0) = 0$ . Assume further that  $u_1 = u_2 = 0$  along the graph of  $f$ . Then in

$$D_{1/2} = \{|x'| < 1, |x_n| < L, x_n > f(x')\}$$

we have

$$0 < C_1 \leq \frac{u_1(x', x_n)}{u_2(x', x_n)} \cdot \frac{u_2(0, L)}{u_1(0, L)} \leq C_2$$

with  $C_1, C_2$  depending only on  $L$ .

**Lemma 2.7** ([JK]). *Let  $D$ ,  $u_1$  and  $u_2$  be as in Lemma 2.6. Assume further that*

$$\frac{u_1(0, L/2)}{u_2(0, L/2)} = 1.$$

*Then,  $u_1(x', x_n)/u_2(x', x_n)$  is Hölder continuous in  $\bar{D}_{1/2}$  for some coefficient  $\alpha$ , both  $\alpha$  and the  $C^\alpha$  norm of  $u_1/u_2$  depending only on  $L$ .*

**Lemma 2.8** ([C2]). *Let  $u$  be as in Lemma 2.6. Then there exists  $c > 0$  depending only on  $L$  such that for  $0 < d < c$ ,  $\frac{\partial u}{\partial x_n}(0, d) \geq 0$  and*

$$C_1 \frac{u(0, d)}{d} \leq \frac{\partial u}{\partial x_n}(0, d) \leq C_2 \frac{u(0, d)}{d}$$

where  $C_i = C_i(M)$ .

**Lemma 2.9** ([JK], Lemma 4.1). *Let  $\Omega$  be Lipschitz domain contained in  $B_{10}(0)$ . There exists a dimensional constant  $\beta_n > 0$  such that for any  $\zeta \in \partial\Omega$ ,  $0 < 2r < 1$  and positive harmonic function  $u$  in  $\Omega \cap B_{2r}(\zeta)$ , if  $u$  vanishes continuously on  $B_{2r}(\zeta) \cap \partial\Omega$ , then for  $x \in \Omega \cap B_r(\zeta)$ ,*

$$u(x) \leq C \left( \frac{|x - \zeta|}{r} \right)^{\beta_n} \sup\{u(y) : y \in \partial B_{2r}(\zeta) \cap \Omega\}$$

where  $C$  depends only on the Lipschitz constants of  $\Omega$ .

Next, we point out that we use the notion of viscosity solutions for our investigation. When  $\{u_0 = 0\}$  is of zero Lebesgue measure, it was proved in [KP] that the viscosity solution of (ST2) is unique and coincides with the usual weak solutions. (See [KP] for the definition as well as other properties of viscosity solutions.) Below we state important properties of viscosity solutions for (ST2) which relates our solutions to the one-phase version of our problem:

$$(ST1) \quad \begin{cases} u_t - \Delta u = 0 & \text{in } \{u > 0\} \\ \frac{u_t}{|Du|} = |Du| & \text{on } \partial\{u > 0\} \\ u(\cdot, 0) = u_0 \geq 0. \end{cases}$$

**Lemma 2.10.** *Suppose  $u$  is a viscosity solution of (ST2). Then*

- (a)  *$u$  is caloric in its positive and negative phases.*
- (b)  *$-u$  is also a viscosity solution of (ST2) with boundary data  $-g$ .*
- (c)  *$u^+ = \max(u, 0)$  (or  $u^- = -\min(u, 0)$ ) is a viscosity subsolution of (ST1) with initial data  $u_0^+$  (or  $u_0^-$ ).*

We say that a pair of functions  $u_0, v_0 : \bar{D} \rightarrow [0, \infty)$  are (strictly) separated (denoted by  $u_0 \prec v_0$ ) in  $D \subset \mathbb{R}^n$  if:

- (i) the support of  $u_0$ ,  $\text{supp}(u_0) = \overline{\{u_0 > 0\}}$  restricted in  $\bar{D}$  is compact and
- (ii)  $u_0(x) < v_0(x)$  in  $\text{supp}(u_0) \cap \bar{D}$ .

**Lemma 2.11** (Comparison principle, [KP]). *Let  $u, v$  be respectively viscosity sub- and supersolutions of (ST2) in  $D \times (0, T) \subset Q$  with initial data  $u_0 \prec v_0$  in  $D$ . If  $u \leq v$  on  $\partial D$  and  $u < v$  on  $\partial D \cap \bar{\Omega}(u)$  for  $0 \leq t < T$ , then  $u(\cdot, t) \prec v(\cdot, t)$  in  $D$  for  $t \in [0, T)$ .*

Below we state a distance estimate for the free boundary and Harnack inequality for the one-phase solution  $u$  of (ST1).

**Lemma 2.12** ([CK], Lemma 2.2). *Let  $u$  be given as in Theorem 2.16. There exists  $t_0 = t_0(N_0, M_0, n) > 0$  such that if  $x_0 \in \Gamma_0$  and  $t \leq t_0$ , then*

$$\frac{1}{C}t^{1/(2-\alpha)} \leq d(x_0, t) \leq Ct^{1/(2-\beta)} \quad (2.1)$$

where  $\alpha$  and  $\beta$  are given in (1.2),  $C$  depends on  $N_0$ ,  $M_0$  and  $n$ , and  $d(x_0, t)$  denotes the distance that  $\Gamma$  moved from the point  $x_0$  during the time  $t$ , i.e.,

$$d(x_0, t) := \sup\{d : u(x_0 + de_n, t) > 0\}.$$

**Lemma 2.13** ([CK], Lemma 2.3). *Let  $u$  be given as in Theorem 2.16. There exists  $d_0$  depending on  $N_0$ ,  $M_0$  and  $n$  such that if  $x_0 \in \Gamma_0$  and  $d \leq d_0$ , then*

$$u(x_0 - de_n, t) \leq Cu(x_0 - de_n, 0) \text{ for } 0 \leq t \leq t(x_0, d)$$

where  $C$  depends on  $N_0$ ,  $M_0$  and  $n$ .

The following monotonicity formula by Alt-Caffarelli-Friedman prevents the scenario that both phases compete with large pressure in our problem.

**Lemma 2.14** ([ACF]). *Let  $h_+$  and  $h_-$  be nonnegative continuous functions in  $B_1(0)$  such that  $\Delta h_{\pm} \geq 0$  and  $h_+ \cdot h_- = 0$  in  $B_1(0)$ . Then the functional*

$$\phi(r) = \frac{1}{r^4} \int_{B_r(0)} \frac{|Dh_+|^2}{|x|^{n-2}} dx \int_{B_r(0)} \frac{|Dh_-|^2}{|x|^{n-2}} dx$$

is monotone increasing in  $r$ ,  $0 < r < 1$ .

**Corollary 2.15.** *Let  $\partial\Omega_0 \subset \mathbb{R}^n$  be star-shaped with respect to  $B_1(0) \subset \Omega_0$  and suppose  $B_{4/3}(0) \subset \Omega_0 \subset B_{5/3}(0)$ . Let  $h_+$  be the harmonic function in  $\Omega_0 - B_1(0)$  with boundary values  $h_+ = 0$  on  $\partial\Omega_0$ , and  $h_+ = 1$  on  $\partial B_1(0)$ . Let  $h_-$  be the harmonic function in  $B_2(0) - \Omega_0$  with boundary values  $h_- = 0$  on  $\partial\Omega_0$ , and  $h_- = 1$  on  $\partial B_2(0)$ . Then there exists a sufficiently large dimensional constant  $M > 0$  such that*

$$\frac{h_+(x_0 - re_n)}{r} \geq M \text{ implies } \frac{h_-(x_0 + re_n)}{r} \leq 1$$

for  $x_0 \in \partial\Omega_0$ ,  $e_n = x/|x|$  and  $0 \leq r \leq 1/6$ .

*Proof.* It follows from Lemma 2.14 since

$$\begin{aligned}
& \left( \frac{h_+(x_0 - re_n)}{r} \cdot \frac{h_-(x_0 + re_n)}{r} \right)^2 \\
& \sim \frac{1}{(2r)^4} \int_{B_{r/2}(x_0 - re_n)} \frac{|Dh_+|^2}{|x - x_0|^{n-2}} dx \cdot \int_{B_{r/2}(x_0 + re_n)} \frac{|Dh_-|^2}{|x - x_0|^{n-2}} dx \\
& \leq \frac{1}{(2r)^4} \int_{B_{2r}(x_0)} \frac{|Dh_+|^2}{|x - x_0|^{n-2}} dx \cdot \int_{B_{2r}(x_0)} \frac{|Dh_-|^2}{|x - x_0|^{n-2}} dx \\
& = \phi(2r) \leq \phi(1/3) \leq C_n.
\end{aligned}$$

□

Lastly, let us finish this section with stating the results obtained in [CK] for the one-phase version of our problem:

$$(ST1) \quad \begin{cases} u_t - \Delta u = 0 & \text{in } \{u > 0\} \\ \frac{u_t}{|Du|} = |Du| & \text{on } \partial\{u > 0\} \end{cases}$$

**Theorem 2.16** ([CK], Theorem 0.1). *Suppose a nonnegative function  $u(x, t)$  is a solution of (ST1) in  $B_2(0) \times [0, 1]$ ,  $0 \in \Gamma_0(u)$ , with the initial data  $u_0 \geq 0$  satisfying (I-b), (I-c) and (I-d) in  $B_2(0)$ . Suppose the initial data satisfies*

$$\{u(x, 0) \geq 0\} = \{x + x_0 : x_n \leq f(x')\}$$

in  $B_1(0)$  where  $f$  is a Lipschitz function with Lipschitz constant  $L < L_n$ . Further, suppose  $u_0(-e_n) = 1$  and  $\sup_{B_2(0) \times [0, 1]} u \leq M_0$ .

Then there exists a small  $c_0 > 0$  depending on  $N_0$ ,  $M_0$  and  $n$  such that the conclusions of Theorem 1.1 holds for  $r \leq c_0$ . Moreover, the following is true: If  $x \in \Gamma_0(u) \cap B_{c_0}(0)$  and  $x + de_n \in \Gamma_t(u) \cap B_{c_0}(0)$ , then

$$C^{-1} \frac{u(x - de_n, 0)}{d} \leq |Du(x + de_n, t)| = V_{x+de_n, t} \leq C \frac{u(x - de_n, 0)}{d}$$

where  $C$  depends on  $n$  and  $M_0$ . Hence

$$\frac{d}{t} \sim |Du(x + de_n, t)| \sim \frac{u(x - de_n, 0)}{d}.$$

Theorem 2.16 states that the free boundary regularizes in a scale proportional to the distance it has traveled. Note that the regularity results hold up to the initial time and all the regularity assumptions are imposed only on the initial data.

### 3 Properties of solutions with star-shaped initial data

**Lemma 3.1.** *If  $\Omega_0$  and  $u_0$  are star-shaped with respect to the ball  $B_{r_0}(0) \subset \Omega_0$ , then  $\Omega_t(u)$  and  $u(\cdot, t)$  stays  $\sigma$ -close to star-shaped for all  $0 \leq t \leq \frac{1}{3}\sigma^{1/5}$ . (See Figure 2)*

*Proof.* 1. Observe that, for any  $a > 0$ , the parabolic scaling  $(x, t) \rightarrow (ax, a^2t)$  preserves both the heat operator and the boundary motion law in (ST2). Therefore, for any  $\sigma > 0$  the function

$$u_1(x, t) := u((1 + \sigma)(x - x_0) + x_0, (1 + \sigma)^2t)$$

is also a viscosity solution of (ST2) with corresponding initial data.

2. Choose  $x_0 \in B_{r_0}(0)$ . Take a small  $c_0 > 0$  such that  $B_{r_0+c_0}(0) \subset \Omega_0$ . We claim that for  $0 \leq \delta \leq \sigma^{6/5}$ ,

$$u_1(x, 0) \leq u(x, \delta) \text{ in } B_R(0) - B_{r_0+c_0}(0) \quad (3.1)$$

if  $\sigma$  is small enough. To show (3.1), let us introduce another function

$$\tilde{u}(x, 0) := u\left(\left(1 + \frac{\sigma}{2}\right)(x - x_0) + x_0, 0\right).$$

Also let  $v^*$  be the solution of the one phase problem (ST1) with initial data  $u_0^-$ , and with  $v^* = 1$  on  $\partial B_R(0)$ . Note also that, due to Lemma,  $u^-$  is a subsolution of (ST1) with initial data  $v^*(x, 0) = u^-(x, 0)$ .

Thus by Theorem 2.11,  $v^* \leq u^-$ . It follows that  $\Omega_t(v^*) \subset \Omega_t(u) \subset \Omega_t(u)$ . Hence by Lemma 2.12 applied for  $-v^*$ ,

$$\Omega_0(\tilde{u}) \subset \Omega_t(u) \text{ for } 0 \leq t \leq \sigma^{7/6}.$$

Moreover, due to our assumption,

$$\tilde{u}(x, 0) \leq u_0(x).$$

Therefore, the maximum principle for caloric functions implies

$$w(x, t) \leq u(x, t)$$

where  $w$  solves the heat equation in the cylindrical domain  $D = \Omega_0(\tilde{u}) \times [0, \sigma^{7/6}]$  with initial data  $\tilde{u}(x, 0)$  and zero boundary data on  $\partial\Omega_0(\tilde{u}) \times [0, \sigma^{7/6}]$ .

Now  $w_t$  solves the heat equation in  $D$ ,

$$w_t = \Delta w \geq -C \text{ at } t = 0, \text{ and } w_t = 0 \text{ on } \partial\Omega_0(\tilde{u}).$$

Therefore we conclude that  $w_t \geq -C$  in  $D$ . In particular

$$w(x, \delta) \geq \tilde{u}(x, 0) - C\delta. \quad (3.2)$$

Next we compare  $u_1(x, 0)$  with  $w(x, \delta)$ . Observe that for  $x \in B_R(0) - B_{r_0+c_0}(0)$ ,

$$\begin{aligned} u_1(x, 0) &= \tilde{u}(x, 0) + \int_{\sigma/2}^{\sigma} ((x - x_0) \cdot Du((1+s)(x - x_0) + x_0, 0)) ds \\ &\leq \tilde{u}(x, 0) - c_0 \sigma^{7/6} \\ &\leq \tilde{u}(x, 0) - C \sigma^{6/5} \\ &\leq w(x, \delta) \leq u(x, \delta) \end{aligned}$$

for  $0 \leq \delta \leq \sigma^{6/5}$ , where the first inequality follows from our assumption (I-d) on  $u_0$ , the second inequality follows if  $\sigma$  is sufficiently small, and the third inequality follows from (3.2). Hence we conclude (3.1).

3. Our goal is to prove that for  $0 \leq \delta \leq \sigma^{6/5}$ ,

$$u_1(x, t) \leq u_2(x, t) := u(x, t + \delta) \quad (3.3)$$

in  $(B_R(0) - B_{r_0+c_0}(0)) \times [0, \sigma^{1/5}]$ . Note that the inequality holds at  $t = 0$  by step 2. However, we need a bit more arguments since we do not know yet whether the lateral boundary data on  $\partial B_{r_0+c_0}(0)$  is properly ordered.

Suppose

$$\Omega(u_1) \subset \Omega(u) \text{ for } 0 \leq t \leq t_0$$

and  $\Omega(u_1)$  contacts  $\partial\Omega(u)$  for the first time at  $t = t_0$ . Observe then that

$$f(x, t) := u(x, t + \delta) - u_1(x, t)$$

solves the heat equation in  $\Omega(u_1)$  with nonnegative boundary data for  $0 \leq t \leq t_0$ , with

$$f(x, 0) \geq 0 \text{ in } B_R(0) - B_{r_0+c_0}(0).$$

Indeed following the computation given above, it follows that

$$f(x, 0) \geq c_0 \sigma \text{ in } B_{r_0+c_0}(0) - B_{r_0+\frac{c_0}{2}}(0).$$

On the other hand, due to the fact that  $w_t \geq -C$  and  $\delta \leq \sigma^{6/5}$ , we have

$$f(x, 0) \geq (w(x, \delta) - w(x, 0)) + (w(x, 0) - u_1(x, 0)) \geq -C \sigma^{6/5} \text{ in } B_{r_0+\frac{c_0}{2}}(0).$$

Therefore we have

$$f(x, t) > 0 \text{ on } \partial B_{r_0+c_0}(0) \times [0, t_0]$$

if  $t_0 \ll 1$ . But then this contradicts Theorem 2.11 applied to the region  $(B_R(0) - B_{r_0+c_0}(0)) \times [0, t_0]$ .

4. From (3.3) of step 3, we obtain

$$u((1+\sigma)(x - x_0) + x_0, (1+\sigma)^2 t) \leq u(x, t + \delta) \quad (3.4)$$

in  $(B_R(0) - B_{r_0+c_0}(0)) \times [0, \sigma^{1/5}]$  for any  $x_0 \in B_{r_0}(0)$ , as long as  $\sigma$  and  $\delta$  are sufficiently small and satisfy  $0 \leq \delta \leq \sigma^{6/5}$ . As a result, for  $0 \leq t \leq \frac{1}{3}\sigma^{1/5}$ , we can choose  $\delta = \sigma(2 + \sigma)t \leq \sigma^{6/5}$  such that

$$(1 + \sigma)^2 t = t + \delta.$$

It follows then from (3.4) that the function  $u(\cdot, t)$  is  $\sigma$ -monotone with respect to the cone of directions  $W_x$  in  $(B_R(0) - B_{r_0+c_0}(0))$  for  $t \in [0, \frac{1}{3}\sigma^{1/5}]$ .

$$\text{( Here } W_x = \{\nu \in S^n : \nu = \frac{x - x_0}{|x - x_0|} \text{ for some } x_0 \in B_{r_0}(0)\}.)$$

□

**Remark 3.2.** For  $x \in \Gamma_0$ , we may let  $e_n = x/|x|$  after a rotation. Then due to  $(I - b)$ ,

$$t(x, d) := \min\left\{\frac{r^2}{u^+(x - re_n, 0)}, \frac{r^2}{u^-(x + re_n, 0)}\right\} \in [r^{7/6}, r^{5/6}] \ll r^{4/5} \quad (3.5)$$

where  $t(x, r)$  is the time it takes for the free boundary to regularize in  $B_r(0)$ . Therefore, we have, for  $0 \leq t \leq t(x_0, r)$ ,

$$u(\cdot, t) \text{ is } r^4\text{-monotone with respect to } W_x \text{ in } (B_R(0) - B_{r_0+c_0}(0)).$$

This property will ensure that our solution  $u$  has its level sets close to Lipschitz graphs in space variable in appropriate scale, which serves as the first step towards the regularization argument: see Lemma 3.6.

**Lemma 3.3. (Harnack at  $t = 0$ )** Let  $u$  be as in Theorem 1.1. For  $x \in \Gamma_0$ , we may let  $e_n = x/|x|$  after a rotation. Then for all  $s > 0$  and for  $0 \leq t \leq t(x, s)$  we have

$$u^+(x - se_n, t) \leq C_1 u^+(x - se_n, 0)$$

and

$$u^-(x + se_n, t) \leq C_1 u^-(x + se_n, 0)$$

where  $e_n = x/|x|$ .

*Proof.* Let  $v^{**}$  solve the one-phase Stefan problem (ST1) with initial data  $v_0^{**}(x) = u_0^+(x)$ . Then  $v^{**}$  is also a solution of (ST2) with  $u_0(x) \leq v_0^{**}(x)$ , and thus by Theorem 2.11 we have

$$u(x, t) \leq v^{**}(x, t).$$

Therefore it follows from one-phase Harnack inequality applied for  $v^{**}(x, t)$  that

$$u^+(x - se_n, t) \leq v^{**}(x - se_n, t) \leq C_1 v^{**}(x - se_n, 0) = C_1 u(x - se_n, 0)$$

for  $0 \leq t \leq t_0$  where  $t_0 = s^2/u(x - se_n, 0) \geq t(x, s)$ .

As for  $u^-(x, t)$ , we compare  $u^-$  with the solution  $v^*$  of (ST1) with initial data  $v_0^*(x) = u_0^-(x)$  and with boundary data  $v^* = 1$  on  $\partial B_R(0)$ . The rest of the argument is parallel to above.

□

**Lemma 3.4. (Backward Harnack at  $t = 0$ )** *Let  $u$  be as in Theorem 1.1. Let  $x \in \Gamma_0$  and let  $e_n = x/|x|$  after a rotation. Then for  $s > 0$  and for  $0 \leq t \leq t(x, s)$*

$$u^+(x - se_n, 0) \leq C_1 u^+(x - se_n, t)$$

and

$$u^-(x + se_n, 0) \leq C_1 u^-(x + se_n, t)$$

*Proof.* We will only show the lemma for  $u^+$ . The other part follows by a parallel argument. Let  $v^*$  solve the one phase problem (ST1) with initial data  $u_0^-$  and with boundary data 1 on  $\partial B_R(0)$ . Then  $-v^*$  is also a solution of (ST2) with  $-v_0^* \leq u_0$ , and thus by Theorem 2.11,  $-v^* \leq u$ . This inequality implies that

$$\{v^* = 0\} \subset \{u \geq 0\}.$$

Note that  $\Omega(v^*)$  moves according to the one-phase dynamics, which has been studied in detail by [CK2]. In particular we know that  $\Omega(v^*)$  will be Lipschitz at each time. Moreover, for a boundary point  $(x, t) \in \Gamma(v^*)$  and  $d := \text{dist}(x, \Gamma_0(v^*))$ , the normal velocity  $V_{x,t}$  satisfies

$$V_{x,t} = |Dv^*(x, t)| \sim \frac{v^*(x + 2de_n, 0)}{2d} \leq d^{\beta-1} \leq t^{\frac{\beta-1}{2-\alpha}} \quad (3.6)$$

where the last inequality follows from Lemma 2.12. Let  $v_*(x, t)$  solve the heat equation in  $\{v^* = 0\}$  with initial data  $u_0(x)$  and boundary data 0 on the lateral boundary of  $\partial\{v^* = 0\}$ , i.e.,  $v_*$  solves

$$\begin{cases} \partial_t v_* - \Delta v_* = 0 & \text{in } \{v^* = 0\} = B_R(0) \times [0, 1] - \Omega(v^*) \\ v_*(x, 0) = u_0(x) & \text{on } \{v^* = 0\} \cap \{t = 0\} \\ v_* = 0 & \text{on } \partial\{v^* = 0\} \cap \{t > 0\}. \end{cases}$$

Since

$$\Omega(v_*) = \{v^* = 0\} \subset \{u \geq 0\},$$

we have  $v_*(x, t) \leq u(x, t)$  in  $\{v^* = 0\}$ . Moreover, for any given  $t > 0$ ,  $\tilde{v}^-(x, s) := v^*(\sqrt{t}x, ts)$  satisfies the assumptions of Lemma 2.5. Thus it follows that  $v^*(\cdot, t)$  is  $t^\alpha$ -close to a harmonic function in  $B_{\sqrt{t}}(x)$  for some  $a > 0$ , where  $x \in \Gamma_0$ . Moreover, due to the assumption on the initial data,  $(v_*)_t = \Delta v_* \geq -C$  at  $t = 0$ . Also on  $\Gamma(v_*)$ ,

$$(v_*)_t / |Dv_*| = -(v^*)_t / |Dv^*| = -|Dv^*| \geq -t^{\frac{\beta-1}{2-\alpha}}.$$

Here the first equality follows since  $(v_*)_t / |Dv_*|$  and  $-(v^*)_t / |Dv^*|$  are the normal velocity of their respective level sets  $\Gamma(v_*)$  and  $\Gamma(v^*)$ , but  $\Gamma(v^*) = \Gamma(v_*)$  by definition. The second equality follows since  $v^*$  solves the one phase problem (ST1), and the last inequality follows from (3.6).

Since  $\Omega(v_*)$  is Lipschitz and  $\Gamma_t(v_*) = \Gamma_t(v^*)$  is regularized in space over time (see Theorem 2.16), (3.6) also holds for  $|Dv_*|$ .

Hence on  $\Gamma(v_*)$ ,

$$(v_*)_t = -|Dv_*||Dv_*| \geq -t^{\frac{2(\beta-1)}{2-\alpha}} > -t^{-2/5}.$$

where  $\alpha$  and  $\beta$  are the growth rates defined in (1.2), and the last inequality follows from the assumption (I-b). Since  $(v_*)_t$  solves a heat equation in  $\Omega(v_*)$ , it follows that for  $x \in \Gamma_0$ ,

$$(v_*)_t \geq -t^{-2/5} \text{ in } B_{\sqrt{t}/2}(x - \sqrt{t}e_n) \times [0, t]. \quad (3.7)$$

Then since  $v_*(x - \sqrt{t}e_n, 0) \geq (\sqrt{t})^\alpha \geq (\sqrt{t})^{7/6} = t^{7/12}$ , for  $x \in \Gamma_0$  we have

$$\begin{aligned} v_*(x - \sqrt{t}e_n, t) &= v_*(x - \sqrt{t}e_n, 0) + \int_0^t (v_*)_t(x - \sqrt{s}e_n, s) ds \\ &\geq v_*(x - \sqrt{t}e_n, 0) - \frac{5}{3}t^{3/5} \\ &\geq \frac{1}{2}v_*(x - \sqrt{t}e_n, 0) + \frac{1}{2}t^{7/12} - \frac{5}{3}t^{3/5} \\ &\geq \frac{1}{2}v_*(x - \sqrt{t}e_n, 0) \end{aligned}$$

if  $t$  is sufficiently small. It follows that

$$\begin{aligned} u^+(x - \sqrt{t}e_n, 0) = v_*(x - \sqrt{t}e_n, 0) &\leq 2v_*(x - \sqrt{t}e_n, t) \\ &\leq 2u^+(x - \sqrt{t}e_n, t) \end{aligned}$$

where the first inequality follows from (3.7).

Since  $\Gamma(v_*) = \Gamma(v^*)$  is Lipschitz in a parabolic scaling,  $v_*$  is almost harmonic. Hence  $v_*(\cdot, t)$  is bigger than the harmonic function  $\omega^t(x)$  in  $\Omega_t(v_*) \cap B_{\sqrt{t}}(x)$  with its value

$$\omega^t(x - \sqrt{t}e_n) = (C_1)^{-1}u^+(x - \sqrt{t}e_n, 0).$$

Note that if  $0 \leq t \leq t(x, s)$ , then  $s < \sqrt{t}$ . Hence for  $0 \leq t \leq t(x, s)$ ,

$$C_1u^+(x - se_n, t) \geq C_1v_*(x - se_n, t) \geq C_1\omega^t(x - se_n) \geq Cu^+(x - se_n, 0),$$

where the last inequality follows since the one-phase result implies a power law on the movement of  $\Gamma(v^*) = \Gamma(v_*)$  (see Lemma 2.5 of [CJK1]), and this yields a bound on  $u^+(x - se_n, 0)/\omega^t(x - se_n)$ .

Similar arguments apply to  $u^-$ , if we consider the function  $v^{**}$  solving (ST1) with initial data  $u_0^+$ , and the function  $v^*$  solving the heat equation in  $\{v^{**} = 0\}$  with initial data  $u_0$  and with boundary data 0 on  $\Gamma(v^{**})$  and  $-1$  on  $\partial B_R(0)$ .  $\square$

**Lemma 3.5. (Distance estimate at  $t = 0$ )** *Let  $u$  be as in Theorem 1.1. Let  $x \in \Gamma_0$  and let  $e_n = x/|x|$  after a rotation. Let  $s$  be a sufficiently small positive constant. If*

$$\frac{|u^+(x - se_n, 0)|}{s} \leq m \quad \text{and} \quad \frac{|u^-(x + se_n, 0)|}{s} \leq m,$$

then for  $t \in [0, \frac{s}{m}]$ ,

$$d(x, t) = \sup\{r : x + re_n \text{ or } x - re_n \in \Gamma_t(u)\} \leq s.$$

*Proof.* Let  $v^{**}$  solve (ST1) with initial data  $u_0^+$ , and let  $v^*$  solve (ST1) with initial data  $u_0^-$  and with  $v^* = 1$  on  $\partial B_R(0)$ . Then by comparison,  $-v^* \leq u \leq v^{**}$  and the lemma follows from the one-phase result Theorem 2.16.  $\square$

In the following lemma, we approximate our solution by harmonic functions.

**Lemma 3.6. (Spatial regularity in the whole domain)** *Let  $u$  be as in Theorem 1.1. Then there exists  $r_0$ : a positive constant depending only on  $n$  and  $N_0$  such that the following holds: For  $x_0 \in \Gamma_0$  and  $0 < r < r_0$ , there exists a function  $\omega(x, t) := \omega^+(x, t) - \omega^-(x, t)$  such that*

- (a)  $\omega(\cdot, t)$  is harmonic in its positive and negative phase in  $(1+r)\Omega_t(u) - (1-r)\Omega_t(u)$ , and  $\Omega(\omega^+)$ ,  $\Omega(\omega^-)$  are star-shaped with respect to  $B_{r_0}(0)$  given in (I-a) ;
- (b) For a dimensional constant  $C > 0$ , we have

$$\omega^+(x, t) \leq u^+(x, t) \leq C\omega^+((1 - r^{5/4})x, t)$$

and

$$\omega^-(x, t) \leq u^-(x, t) \leq C\omega^-((1 + r^{5/4})x, t)$$

in  $B_r(x_0) \times [r^2, t(x_0, r)]$ .

Note that  $t(x_0, r) \geq r^{7/6} \geq r^2$ , and  $\partial\{\omega^+ > 0\}$  need not be  $\partial\{\omega^- > 0\}$ .

**Remark 3.7.** *Note that, due to Lemma 3.1, We know that the re-scaled function  $\tilde{u}(x, t)$  as given (1.4) satisfies condition (B') in space variable. On the other hand, it is not clear whether the level sets of  $u$  are close to Lipschitz graphs in time variable. The approximation by harmonic functions given by Lemma 3.6 as well as Harnack-type inequalities obtained at  $t = 0$  and at future times will ensure us that  $\Gamma(u)$  is Lipschitz in time variable as well, which would serve as the first step towards the regularization procedure in section 5.*

*Proof.* 1. We will only show the lemma for  $u^+$ . For given  $x_0 \in \Gamma_0$ , we may assume that  $e_n = \frac{x_0}{|x_0|}$  after a rotation.

First we will construct a barrier function  $v_1$  which will serve as a supersolution of (ST2). For this, let us first consider  $u^*$ : the viscosity solution of

(ST1) with the initial data  $u_0^+$  for  $0 \leq t \leq t_0$ . We may assume that for  $t_0$  small compared to  $R$  the support of  $u^*$  stays inside  $B_R(0)$ . Let us define

$$\Omega_+^* := \{u^* > 0\}, \quad \Gamma^* := \partial\{u^* = 0\}, \quad \Omega_-^* := B_R(0) \times [0, t_0] - \overline{\Omega_+^*}.$$

Now let  $v_1$  solve the heat equation in  $\Omega_+^*$  and in  $\Omega_-^*$ , with initial data  $u_0$  and with  $v_1 = -1$  on  $\partial B_R(0)$ . In other words,  $v_1 = v_1^+ - v_1^-$  where

$$\begin{cases} \partial_t v_1^+ - \Delta v_1^+ = 0 & \text{in } \Omega_+^* \\ v_1^+(x, 0) = u_0^+(x) & \text{on } \{t = 0\} \\ v_1^+ = 0 & \text{on } \Gamma^* \end{cases}$$

and

$$\begin{cases} \partial_t v_1^- - \Delta v_1^- = 0 & \text{in } \Omega_-^* \\ v_1^-(x, 0) = u_0^-(x) & \text{on } \{t = 0\} \\ v_1^- = 0 & \text{on } \Gamma^* \\ v_1^- = 1 & \text{on } \partial B_R(0) \times [0, 1]. \end{cases}$$

Note that  $v_1$  solves the heat equation in two regions  $\Omega_+^*$  and  $\Omega_-^*$ , with free boundary  $\Gamma^*$ . Also note that  $v_1^+ = u^*$  and  $\partial_t v_1^+ = |Dv_1^+|^2$  on  $\Gamma^*$  since the boundary  $\Gamma^*$  is obtained from the one phase problem with initial data  $u_0^+$ . Hence we can observe that  $v_1$  is a supersolution of the two-phase problem (ST2).

Similarly one can construct a subsolution of (ST2): let us consider  $\tilde{u}^*$ : the viscosity solution of (ST1) in  $B_R(0) \times [0, t_0]$  with the initial data  $u_0^-$  and fixed boundary data 1 on  $\partial B_R(0) \times [0, t_0]$ . Let us define

$$\tilde{\Omega}_-^* := \{\tilde{u}^* > 0\}, \quad \tilde{\Gamma}^* := \partial\{\tilde{u}^* = 0\}, \quad \tilde{\Omega}_+^* := B_R(0) \times [0, t_0] - \overline{\tilde{\Omega}_-^*}.$$

Now let  $v_2$  solve the heat equation in two regions  $\tilde{\Omega}_-^*$  and  $\tilde{\Omega}_+^*$ , with boundary data 0 on  $\tilde{\Gamma}^*$  and  $-1$  on  $\partial B_R(0)$ , and with initial data  $u_0$ . Note that  $v_2^- = \tilde{u}^*$ . Then  $v_2$  is a subsolution of (ST2), and by comparison,

$$v_2 \leq u \leq v_1. \tag{3.8}$$

Hence the free boundary of  $u$  is trapped between the free boundaries of  $v_1$  and  $v_2$ . Note that the free boundaries  $\Gamma^*$  and  $\tilde{\Gamma}^*$  of  $v_1$  and  $v_2$  are obtained from the one-phase problem (ST1). Hence by (a) of Theorem 2.16,  $\Gamma^*$  and  $\tilde{\Gamma}^*$  are Lipschitz in space in  $B_d(x_0)$  for a small constant  $d > 0$ . Also, (c) of Theorem 2.16 implies that for  $\delta \in [d/2, d]$  and  $x_0 + \delta e_n \in \Gamma_t^*$ , the normal velocity  $V_{x_0 + \delta e_n, t}$  of  $\Gamma^*$  at  $(x_0 + \delta e_n, t)$  satisfies

$$V_{x_0 + \delta e_n, t} = |Dv_1^+(x_0 + \delta e_n, t)| \sim \frac{d}{t} \sim \frac{u_0^+(x_0 - \delta e_n)}{d} \leq d^{\beta-1}.$$

Since  $d/t \leq d^{\beta-1}$ , we obtain

$$t \geq d^{2-\beta} > d^2.$$

Hence the above speed bound of  $\Gamma^*$  implies that  $\Omega_+^*$  and  $\Omega_-^*$  are Lipschitz in space and time, in parabolic scaling. Then by Lemma 2.5,  $v_1^+$  and  $v_1^-$  are almost harmonic up to  $d$ -neighborhood of their free boundaries for  $t \geq d^2$ . Similarly, we obtain that  $v_2^+$  and  $v_2^-$  are almost harmonic up to  $d$ -neighborhood of their free boundaries for  $t \geq d^2$ .

Next we fix  $r \leq d$ . Note that if  $t \leq t(x_0, r)$ , then by (c) of Theorem 2.16, both of the sets  $\Gamma_t(v_1)$  and  $\Gamma_t(v_2)$  are within distance  $r$  of  $\Gamma_0(u)$  in  $B_r(x_0)$  during this time. In particular, parallel arguments as in the proof of Lemmas 2.1 and 2.3 in [CK] yields that

$$\sup\{u(y, s) : (y, s) \in B_d(x_0) \times [0, d^2]\} \sim u(x - de_n, 0).$$

Now using the almost harmonicity of  $v_1^+$  and  $v_2^+$ , we conclude that for  $0 \leq t \leq t(x_0, r)$

$$v_2(x_0 - 2re_n, t) \sim u_0(x_0 - 2re_n, 0) \sim v_1(x_0 - 2re_n, t). \quad (3.9)$$

2. Observe that by the definition of  $t(x_0, r)$  and the assumption on the growth rates of  $u_0$ ,

$$r^{2-\beta} \leq t(x_0, r) \leq r^{2-\alpha} \leq r^{5/6} := \tau. \quad (3.10)$$

Due to Lemma 3.1, we know that at each time,  $\Omega_t(u)$  is  $\tau^5$ -close to a star-shaped domain  $D_t$  up to the time  $t = \tau$ , i.e.,

$$D_t \subset \Omega_t(u) \subset (1 + \tau^5)D_t \subset (1 + r^4)D_t \quad (3.11)$$

for  $0 \leq t \leq \tau$ . Also note that by the first inequality of (3.10) with  $\beta \geq 5/6$ ,

$$t(z, r^{13/20}) \geq r^{13(2-\beta)/20} > \tau \text{ for any } z \in \Gamma_0.$$

Hence we can apply Lemma 3.3 for  $s = r^{13/20}$  up to the time  $\tau$ . Then by Lemma 3.3 and (3.11) with  $\beta \geq 5/6$ ,

$$u(x, t) \leq r^{(13/20)(5/6)} = r^{13/24}$$

for  $x \in \partial(1 - r^{13/20})D_0$  and for  $0 \leq t \leq \tau$ . Then by the  $\tau^5$ -monotonicity of  $u$ ,

$$u(x, t) \leq r^{13/24} \text{ on } B_R(0) - (1 - r^{13/20} + r^4)D_0 \quad (3.12)$$

for  $0 \leq t \leq \tau$ . Since  $\Gamma_t(u)$  is located between  $\Gamma^*$  and  $\tilde{\Gamma}^*$ ; the free boundaries of one-phase problem, Lemma 2.12 with  $\beta \geq 5/6$  implies that  $\Gamma(u)$  stays in the  $\tau^{6/7}$ -neighborhood of  $\Gamma_0(u)$  up to  $\tau$ . Also (3.11) implies that  $\partial D_t$  stays in the  $\tau^5$ -neighborhood of  $\Gamma_t(u)$  up to  $\tau$ . Hence we obtain that  $\partial D_t$  stays in the

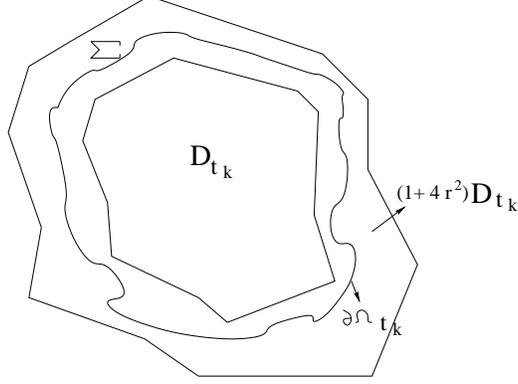

Figure 2: Approximation of the positive phase by a star-shaped domain

$\tau^{5/6}$ -neighborhood of  $\partial D_0$  up to the time  $\tau$ . Since  $\tau^{5/6} = r^{25/36} < r^{13/20}$ , (3.12) implies

$$u(x, t) \leq r^{13/24} \text{ on } B_R(0) - D_s \quad (3.13)$$

for any  $0 \leq s, t \leq \tau$ .

3. Let

$$t_0 = 0 \leq t_1 = r^2 \leq t_2 = 2r^2 \leq \dots \leq t_{k_0} = k_0 r^2 \leq \tau$$

and fix a number  $b$  such that

$$5/4 \leq b < 61/48.$$

We will construct a supersolution of (ST2) in

$$(B_R(0) - (1 + r^b)D_{t_k}) \times [t_k, t_{k+1}].$$

Let  $w^k(x)$  be the harmonic function in

$$\Sigma := (1 + 4r^b)D_{t_k} - D_{t_k}$$

with boundary data zero on  $\partial(1 + 4r^b)D_{t_k}$  and  $C_n r^{13/24}$  on  $\partial D_{t_k}$ , where  $C_n$  is a sufficiently large dimensional constant. Extend  $w^k(x) = 0$  in  $\mathbb{R}^n - \Sigma$ . Next define

$$\Phi^k(x, t) := \inf\{w^k(y) : |x - y| \leq r^b - (t - t_k)\frac{r^{b-2}}{2}\}$$

in  $(B_R(0) - (1 + r^b)D_{t_k}) \times [t_k, t_{k+1}]$ . We claim that  $\Phi^k$  is a supersolution of (ST2) in  $(B_R(0) - (1 + r^b)D_{t_k}) \times [t_k, t_{k+1}]$ , since our constant  $b$  satisfies

$$r^{b-2} > r^{\frac{13}{24}-b}. \quad (3.14)$$

For simplicity, denote  $\Phi = \Phi^k$ . To check that  $\Phi$  is a supersolution, first note that  $\Phi(\cdot, t)$  is superharmonic in its positive set and  $\Phi_t \geq 0$ . Hence we only need to show that

$$\frac{\Phi_t}{|D\Phi|} \geq |D\Phi| \text{ on } \Gamma(\Phi). \quad (3.15)$$

Due to the definition of  $\Phi$ ,  $\Gamma_t(\Phi)$  has an interior ball of radius at least  $r^b/2$  for  $t_k \leq t \leq t_{k+1}$ . This and the superharmonicity of  $\Phi$  in the positive set yield that

$$|D\Phi| \leq \frac{Cr^{13/24}}{r^b} \text{ on } \Gamma(\Phi)$$

for a dimensional constant  $C > 0$ . Moreover  $\Gamma(\Phi)$  evolves with normal velocity  $\frac{1}{2}r^{b-2}$ . Since (3.14) holds for our choice of  $b$  (i.e., for  $5/4 \leq b < 61/48$ ), we conclude (3.15) for  $r$  smaller than a dimensional constant  $r(n)$ . Now we compare  $u$  with  $\Phi$  in

$$(B_R(0) - (1 + r^b)D_{t_k}) \times [t_k, t_{k+1}].$$

Note that by (3.13),

$$u^+ \leq \Phi \text{ on } \partial(1 + r^b)D_{t_k}$$

if  $C_n$  is chosen sufficiently large. Also at  $t = t_k$ , (3.11) implies

$$u(\cdot, t_k) \leq 0 \leq \Phi(\cdot, t_k) \text{ on } B_R(0) - (1 + r^b)D_{t_k}.$$

Hence we get  $u \leq \Phi$  in  $(\mathbb{R}^n - (1 + r^b)D_{t_k}) \times [t_k, t_{k+1}]$ . This implies

$$\Omega(u) \subset \Omega(\Phi) \cup ((1 + r^b)D_{t_k} \times [t_k, t_{k+1}]) := \tilde{\Omega}(\Phi) \quad (3.16)$$

for  $t_k \leq t \leq t_{k+1}$ .

4. Next we let  $v(x, t)$  solve the heat equation in

$$\tilde{\Omega}(\Phi) - ((1 - 3r)\Omega_0(u) \times [t_k, t_{k+1}])$$

with initial data  $v(\cdot, t_k) = u(\cdot, t_k)$  and boundary data zero on  $\Gamma(\Phi)$  and  $v = u$  on  $(1 - 3r)\Gamma_0(u)$ . Observe that, due to (3.16), we have

$$u^+ \leq v \text{ for } t_k \leq t \leq t_{k+1}. \quad (3.17)$$

Since  $\tilde{\Omega}(\Phi)$  is star-shaped and expands with its normal velocity  $< r^{b-2}$  which is less than  $r^{-1}$ , Lemma 2.5 applies to  $\tilde{v}(x, t) := v(rx, r^2t)$ . In particular there exists a constant  $C > 0$  such that

$$(1/C)v(x, t) \leq h_1(x, t) \leq Cv(x, t)$$

for  $(t_k + t_{k+1})/2 \leq t \leq t_{k+1}$ , where  $h_1(\cdot, t)$  is the harmonic function in  $\Omega_t(v) - (1 - 2r)\Omega_0(u)$  with boundary data zero on  $\Gamma_t(v)$  and  $v$  on  $(1 - 2r)\Gamma_0(u)$ .

Hence we conclude that

$$u^+ \leq v \leq Ch_1$$

in  $(B_R(0) - (1 - 2r)\Omega_0(u)) \times [(t_k + t_{k+1})/2, t_{k+1}]$ .

5. Similar arguments, now pushing the boundary purely by the minus phase given by the harmonic function yield that

$$\Pi_t := \{x \in D_{t_k} : \text{dist}(x, \partial D_{t_k}) \geq 3r^b + \frac{r^{b-2}}{2}(t - t_k)\} \subset \Omega_t(u)$$

for  $t_k \leq t \leq t_{k+1}$ . Let  $w(x, t)$  solve the heat equation in

$$\Pi - ((1 - 3r)\Omega_0(u) \times [t_k, t_{k+1}]))$$

with initial data  $u(\cdot, t_k)$  and boundary data zero on  $\partial\Pi$ , and  $u$  on  $(1 - 3r)\Gamma_0(u)$ . Then  $u \geq w(x, t)$ . Since  $\Pi$  is star-shaped and it shrinks with its normal velocity  $< r^{b-2}$  which is less than  $r^{-1}$ , Lemma 2.5 applies to  $\tilde{w}(x, t) := w(rx, r^2t)$ . In particular there exists  $C > 0$  such that

$$u^+ \geq w \geq (1/C)h_2$$

for  $(t_k + t_{k+1})/2 \leq t \leq t_{k+1}$ , where  $h_2(\cdot, t)$  is the harmonic function in  $\Pi_t - (1 - 2r)\Omega_0(u)$  with boundary data coinciding with that of  $w$ .

6. Lastly we will show that  $h_1$  and  $h_2$  are not too far away, i.e.

$$h_1(x, t) \leq Ch_2(x - 8r^b e_n, t) \quad (3.18)$$

with a dimensional constant  $C > 0$ . Since  $u$  is between  $(1/C)h_2$  and  $Ch_1$ , this will conclude our lemma for  $(t_k + t_{k+1})/2 \leq t \leq t_{k+1}$ . Then by changing the time intervals  $[t_k, t_{k+1}]$  to  $[t_k + r^2/2, t_{k+1} + r^2/2]$ , we obtain lemma for any  $t \in [r^2, t(x_0, r)]$ .

To prove (3.18), observe that by the construction of  $v$  and  $w$ ,

$$\Omega_t(w) \subset \Omega_t(v) \subset (1 + 8r^b)\Omega_t(w).$$

On the other hand, since  $t_{k+1} - t_k = r^2$ , Lemma 2.12 implies

$$\sup\{d(x, \Gamma_t(u)) : x \in \Gamma_{t_k}(u)\} \leq r^{12/7}$$

for  $t \in [t_k, t_{k+1}]$ . Then by (3.11),

$$\sup\{d(x, \Gamma_t(u)) : x \in \partial D_{t_k}\} \leq r^{12/7} + r^4 \ll r^b \quad (3.19)$$

for  $t \in [t_k, t_{k+1}]$ . Then we obtain

$$v_2(x, t) \leq v(x, t) \leq v_1((1 - 4r^b)x, (1 - 4r^b)^2(t - t_k) + t_k) \quad (3.20)$$

for  $t_k \leq t \leq t_{k+1}$ , where the first inequality follows from (3.8) and (3.17), and the second inequality follows from the comparison principle with (3.8),  $v(\cdot, t_k) = u(\cdot, t_k)$  and (3.19). Similarly,

$$v_2((1 + 4r^b)x, (1 + 4r^b)^2(t - t_k) + t_k) \leq w(x, t) \leq v_1(x, t). \quad (3.21)$$

Combing (3.20) and (3.21), we get

$$\begin{aligned} v_2((1 + 4r^b)x, (1 + 4r^b)^2(t - t_k) + t_k) &\leq w(x, t), v(x, t) \\ &\leq v_1((1 - 4r^b)x, (1 - 4r^b)^2(t - t_k) + t_k). \end{aligned}$$

This and (3.9) yield

$$v(x_0 - 2re_n, t) \sim w(x_0 - 2re_n, t) \sim u(x_0 - 2re_n, 0).$$

It follows that

$$w(x, t) \leq v(x, t) \leq Cw(x - 8r^b e_n, t) \text{ on } (1 - 2r)\Gamma_0 \times [t_k, t_{k+1}].$$

Hence due to Dahlberg's lemma, we conclude that

$$h_1(x, t) \leq C_1 v(x, t) \leq C_2 w(x - 8r^b e_n, t) \leq C_3 h_2(x - 8r^b e_n, t)$$

in  $B_r(x_0) \times [(t_k + t_{k+1})/2, t_{k+1}]$ . Since the inequality holds for any  $5/4 \leq b < 61/48$ , we can conclude the lemma.  $\square$

Next we show that in the “unbalanced” region, where one phase has much larger flux than the other, the regularization process occurs similarly to the one in the one-phase problem. This observation will be useful for the analysis in section 4.

**Proposition 3.8. (Regularization in unbalanced region I)** *Let  $u$  be as given in Theorem 1.1. For a fixed  $x_0 \in \Gamma_0(u)$ , we may let  $e_n = x_0/|x_0|$  after a rotation. Suppose that either*

$$u^+(x_0 - re_n, 0) \geq Mu^-(x_0 + re_n, 0)$$

or

$$u^-(x_0 + re_n, 0) \geq Mu^+(x_0 - re_n, 0)$$

for  $M > M_n$ , where  $M_n$  is a sufficiently large dimensional constant. Then for  $r \leq 1/M_n$ , there exists a dimensional constant  $C > 0$  such that

$$|Du^+(x, t)| \leq C \frac{u^+(x_0 - re_n, 0)}{r} \quad \text{and} \quad |Du^-(x, t)| \leq C \frac{u^-(x_0 + re_n, 0)}{r}$$

in  $B_r(x_0) \times [t(x_0, r)/2, t(x_0, r)]$ .

**Remark 3.9.** 1. *In the next section, we will extend Proposition 3.8 for later times, i.e., for  $x_0 \in \Gamma_{t_0}$ . (See Lemma 4.7.)*

2. *Note that the situation given in Proposition 3.8 is essentially a perturbation of the one-phase case in [CK]. The main step in the proof is in verification of this observation: i.e., by barrier arguments we will show that our solution is very close to a re-scaled version of the one-phase solution, for which the regularity of solutions are well-understood (see Theorem 2.16).*

*Proof.* Without loss of generality, we may assume that

$$u^+(x_0 - re_n, 0) \geq Mu^-(x_0 + re_n, 0).$$

1. First we will show that after a small amount of time  $u$  becomes almost harmonic near the free boundary. Lemmas 3.3 and 3.4 imply that for  $0 \leq t \leq t(x_0, r)$ ,

$$u^+(x_0 - re_n, t) \sim u^+(x_0 - re_n, 0), \quad u^-(x_0 + re_n, t) \sim u^-(x_0 + re_n, 0) \quad (3.22)$$

Also note that, by the assumption on the initial data  $u_0$ , Lemma 3.6 holds at  $t = 0$ . In other words, there exists a function  $\omega(x, 0) = \omega_0(x)$  such that

- (a)  $\omega_0$  is harmonic in its positive and negative phases in  $(1+r)\Omega_0(u) - (1-r)\Omega_0(u)$ ;
- (b)  $\Omega(\omega_0^+)$  and  $\Omega(\omega_0^-)$  are star-shaped;
- (c) In  $B_r(x_0)$ , we have

$$\omega_0^+(x) \leq u_0^+(x) \leq C\omega_0^+((1-r^{5/4})x) \quad (3.23)$$

and

$$\omega_0^-(x) \leq u_0^-(x) \leq C\omega_0^-((1+r^{5/4})x). \quad (3.24)$$

Next we will improve (3.23) and (3.24) for later times to obtain the inequalities with  $C = (1+r^\alpha)$  for  $t \geq r^{3/2}$ . By the distance estimate-Lemma 2.12, the free boundary of  $u$  moves less than  $r^{9/7} < r^{5/4}$  during the time  $t = r^{3/2}$ . Then we let  $v_1$  solve

$$\left\{ \begin{array}{ll} \partial_t v_1 = \Delta v_1 & \text{in } (1+2r^{5/4})\Omega_0(\omega^+) \times [0, r^{3/2}] \\ \partial_t v_1 = \Delta v_1 & \text{in } (B_R(0) - (1+2r^{5/4})\overline{\Omega_0}(\omega^+)) \times [0, r^{3/2}] \\ v_1(\cdot, 0) = u_0^+ & \text{on } (1+2r^{5/4})\Omega_0(\omega^+) \\ v_1(\cdot, 0) = -u_0^- & \text{on } B_R(0) - (1+2r^{5/4})\overline{\Omega_0}(\omega^+) \\ v_1 = 0 & \text{on } (1+2r^{5/4})\Gamma_0(\omega^+) \times [0, r^{3/2}] \\ v_1 = -1 & \text{on } \partial B_R(0) \times [0, r^{3/2}]. \end{array} \right.$$

Similarly, we let  $v_2$  solve the heat equation in two cylindrical regions

$$(1-2r^{5/4})\Omega_0(\omega^+) \times [0, r^{3/2}] \text{ and } (B_R(0) - (1-2r^{5/4})\overline{\Omega_0}(\omega^+)) \times [0, r^{3/2}]$$

with initial data  $u_0^+$  and  $-u_0^-$ , and with lateral boundary data zero on  $(1-2r^{5/4})\Gamma_0(\omega^+) \times [0, r^{3/2}]$  and  $-1$  on  $\partial B_R(0) \times [0, r^{3/2}]$ . Then by comparison,

$$v_2 < u < v_1. \quad (3.25)$$

Also by Lemma 2.5 with  $\beta \geq 5/6$ ,

$$|v_1 - v_2| \leq r^{\frac{5}{4} \times \frac{5}{6}} = r^{25/24}.$$

Note that on  $(1-r^{6/7})\Gamma_0(\omega^+)$ ,

$$|v_1| \geq r^{\frac{6}{7}\alpha} \geq r^{\frac{6}{7} \times \frac{7}{6}} = r$$

and thus for  $a_1 = 1/24$ ,

$$|v_1 - v_2| \leq r^{a_1} |v_1| \text{ on } (1 - r^{6/7})\Gamma_0(\omega^+). \quad (3.26)$$

Similarly,

$$|v_1 - v_2| \leq r^{a_1} |v_2| \text{ on } (1 + r^{6/7})\Gamma_0(\omega^+). \quad (3.27)$$

By Lemma 2.5,  $v_1$  and  $v_2$  are almost harmonic in the  $r^{3/4}$ -neighborhood of their boundaries for  $\frac{1}{2}r^{3/2} \leq t \leq r^{3/2}$ . Then the almost harmonicity of  $v_1$  and  $v_2$  with (3.25), (3.26) and (3.27) imply the following: for  $\frac{1}{2}r^{3/2} \leq t \leq r^{3/2}$ , there exist positive harmonic functions  $\tilde{\omega}^+(\cdot, t)$  and  $\tilde{\omega}^-(\cdot, t)$  defined respectively in

$$\Omega_t(v_2^+) \cap (B_R(0) - (1 - r^{1-b})\Omega_0(\omega^+)) \text{ and } \Omega_t(v_1^-) \cap (1 + r^{1-b})\Omega_0(\omega^+)$$

where  $b = 1/7$ , such that for some  $a > 0$

$$\tilde{\omega}^+(x, t) \leq u^+(x, t) \leq (1 + r^a)\tilde{\omega}^+((1 - 4r^{5/4})x, t) \quad (3.28)$$

and

$$\tilde{\omega}^-(x, t) \leq u^-(x, t) \leq (1 + r^a)\tilde{\omega}^-((1 + 4r^{5/4})x, t). \quad (3.29)$$

Now on the time interval  $[0, r^{3/2}] + \frac{k}{2}r^{3/2}$ ,  $1 \leq k \leq m$ , we construct  $v_1$  and  $v_2$  so that they solve the heat equation in the cylindrical domains with

$$\Gamma(v_1) = (1 + 2r^{5/4})\Gamma_{\frac{k}{2}r^{3/2}}(\omega^+) \times [\frac{k}{2}r^{3/2}, (1 + \frac{k}{2})r^{3/2}]$$

and

$$\Gamma(v_2) = (1 - 2r^{5/4})\Gamma_{\frac{k}{2}r^{3/2}}(\omega^+) \times [\frac{k}{2}r^{3/2}, (1 + \frac{k}{2})r^{3/2}].$$

Then by a similar argument as above, we obtain harmonic functions  $\tilde{\omega}^\pm(\cdot, t)$  satisfying (3.28) and (3.29) for

$$\frac{1+k}{2}r^{3/2} \leq t \leq (1 + \frac{k}{2})r^{3/2}.$$

Hence we conclude (3.28) and (3.29) for  $r^{3/2} \leq t \leq t(x_0, r)$ .

2. Next we re-scale  $u(x, t)$  as follows:

$$\tilde{u}(x, t) := \alpha^{-1}u(rx + x_0, r^2\alpha^{-1}t) \text{ in } 2Q_{x_0},$$

where  $\alpha := u^+(x_0 - re_n, 0) \ll r^{1/2}$ . Then  $\tilde{u}(x, t)$  solves

$$\begin{cases} (\alpha\partial_t - \Delta)\tilde{u} = 0 & \text{in } \Omega(\tilde{u}) \\ V = |D\tilde{u}^+| - |D\tilde{u}^-| & \text{on } \Gamma(\tilde{u}) \\ \tilde{u}(-e_n, 0) = 1 \\ \tilde{u}(e_n, 0) = -1/N & \text{where } N \geq M. \end{cases}$$

Furthermore, (3.22) implies that for  $0 \leq t \leq 1$ ,

$$\tilde{u}^+(-e_n, t) \sim 1, \quad \tilde{u}^-(e_n, t) \sim \frac{1}{N}.$$

Let  $\tilde{w}$  be the corresponding re-scaled version of  $\tilde{\omega}$  given in (3.28) and (3.29), then in  $B_{r^{-b}}(0) \cap \Omega_0(\tilde{u})$  we have

$$(1 - r^a)\tilde{w}^+((1 + 4r^{5/4})x, \alpha r^{-1/2}) \leq \tilde{u}^+(x, \alpha r^{-1/2}) \leq \tilde{w}^+(x, \alpha r^{-1/2}) \quad (3.30)$$

and

$$(1 - r^a)\tilde{w}^-(x, \alpha r^{-1/2}) \leq \tilde{u}^-(x, \alpha r^{-1/2}) \leq \tilde{w}^-((1 + 4r^{5/4})x, \alpha r^{-1/2}) \quad (3.31)$$

Here note that

$$\alpha r^{-1/2} = \sqrt{r} \cdot \frac{u^+(x_0 - r e_n, t_0)}{r} \leq r^{1/3}.$$

Lastly, for given  $x_0 \in \Gamma(\tilde{u}) \cap B_1(0)$ , a similar argument as in (3.7) implies that

$$\tilde{u}(x, t) \leq (1 + r^b)\tilde{u}(x, 0) \text{ in } \partial B_{\frac{1}{2}r^{-b}}(r^{-b}e_n) \times [0, 1]. \quad (3.32)$$

3. We claim that we can construct a supersolution  $U_1$  and a subsolution  $U_2$  of (ST2) such that

$$U_2(x, t) \leq \tilde{u}(x, t) \leq U_1(x, t) \leq U_2(x - \sqrt{\epsilon}e_n, t) \text{ in } B_1(0) \times [\alpha r^{-1/2}, 1]$$

and that  $U_2$  is a smooth solution with uniformly Lipschitz boundary in space and time. Then for sufficiently small  $r > 0$  the lemma will follow from analysis parallel to that of [ACS2].

To illustrate the main ideas, let us first assume that

- (a) (3.30) and (3.31) hold in the entire ring domain  $\mathcal{R} \times [0, 1]$ , where

$$\mathcal{R} := \{x : d(x, \Gamma_0(\tilde{u})) \leq r^{-b}\};$$

- (b)  $\tilde{u}(x, t) \leq (1 + r^b)\tilde{u}(x, 0)$  on  $\partial\mathcal{R} \times [0, 1]$ .

Let

$$\Sigma := \{x : d(x, \mathbb{R}^n - \Omega_0) \leq r^{-b}\} \times [\alpha r^{-1/2}, 1],$$

and let  $U_1^+$  be the solution of the one-phase Hele-Shaw problem in  $\Sigma$ :

$$(HS) \quad \begin{cases} \Delta U_1^+ = 0 & \text{in } \{U_1^+ > 0\} \cap \Sigma; \\ \partial_t U_1^+ = |DU_1^+|^2 & \text{on } \partial\{U_1^+ > 0\} \cap \Sigma; \\ U_1^+(x, \alpha r^{-1/2}) = \tilde{w}^+(x, \alpha r^{-1/2}) & ; \\ U_1^+(x, t) = (1 + r^b)\tilde{u}(x, 0) & \text{for } x \in \partial\Sigma \end{cases}$$

Let

$$U_1 = U_1^+ - U_1^- \text{ in } \mathcal{R} \times [\alpha r^{-1/2}, 1],$$

where  $U_1^-(\cdot, t)$  is the harmonic function in  $\mathcal{R} - \Omega(U_1^+)$  with boundary data

$$U_1^- = 0 \text{ on } \Gamma(U_1^+), \quad U_1^- = C/N \text{ on } \partial\mathcal{R} - \Omega(U_1^+).$$

Then  $U_1$  is a supersolution of (ST2) in  $\Sigma$ , and thus by Theorem 2.11 and the assumptions (a)-(b) we have  $\tilde{u} \leq U_1$  in  $\Sigma$ .

4. The construction of the subsolution  $U_2$  is a bit less straightforward. We use

$$U_2^+(x, t) := (1 - \epsilon) \sup_{|y-x| \leq \sqrt{\epsilon}(1-c(t))} U_1^+((1 + \sqrt{\epsilon})y, t),$$

where  $\epsilon = 1/N$  and  $c(t) := t^{4/5}$ . Then we define

$$U_2 = U_2^+ - U_2^- \text{ in } R \times [\alpha r^{-1/2}, 1],$$

where  $\mathcal{R}$  is the ring domain as given above and  $U_2^-(\cdot, t)$  is the harmonic function in  $R - \Omega(U_2^+)$  with fixed boundary data zero on  $\Gamma(U_2^+)$  and  $C/N$  on  $\partial\mathcal{R} - \Omega(U_2^+)$ . Then  $U_2$  satisfies the free boundary condition

$$V_{U_2} \leq (1 + \epsilon)|DU_2^+| - \sqrt{\epsilon}c'(t).$$

Therefore,  $U_2$  is a subsolution of (ST2) if we can show that

$$\sqrt{\epsilon}c'(t) \geq \epsilon|DU_2^+| + |DU_2^-| \text{ on } \Gamma(U_2) \quad (3.33)$$

and  $\int_0^1 c'(s)ds \leq 1$ .

The analysis performed in [CK], as in the proof of (c) of Theorem 2.16, yields the following: at a fixed time  $t$ ,  $\Gamma(U_1)$  regularizes in the scale of  $d := d(t)$  which solves

$$t = \frac{d^2}{U_1(-de_n, 0)}.$$

Therefore,

$$|DU_2^+| \sim \frac{U_2^+(-de_n, 0)}{d} \text{ and } |DU_2^-| \sim \frac{U_2^-(de_n, 0)}{d}$$

on

$$\Gamma(U_2) \times [t/2, t].$$

Observe that since  $\beta \geq 5/6$ ,

$$U_2^+(-de_n, 0) \leq d^{5/6} \text{ and } U_2^-(de_n, 0) \leq \epsilon d^{5/6},$$

then we have

$$\epsilon \frac{U_2^+(-de_n, 0)}{d} + \frac{U_2^-(de_n, 0)}{d} \leq \epsilon d^{-1/6} \leq \sqrt{\epsilon} t^{-1/5}.$$

where the last inequality follows from

$$t = d^2/U_1(-de_n, 0) \leq d^2/d^\alpha \leq d^{5/6}.$$

Hence  $c(t) = t^{4/5}$  satisfies (3.33), and we conclude that  $U_2$  is a subsolution of (ST2) in  $\Sigma$ .

Now we can use the fact

$$U_2 \leq \tilde{u} \leq U_1 \text{ in } B_c(0) \times [\alpha r^{-1/2}, c]$$

to conclude that  $\tilde{u}$  is  $\sqrt{\epsilon}$ -close to  $U_1$ : a Lipschitz (and smooth) solution in  $B_1(0) \times [1/2, 1]$ , confirming (B'). Moreover (A) holds due to Lemma 3.3 and Lemma 3.4. Once we can confirm this, we can conclude by the results of [ACS2] with the choice of a sufficiently small  $\epsilon$ .

5. Now we proceed to the general proof without the simplified assumptions (a) and (b) in step 3, which are replaced with local inequalities (3.30)-(3.31) and (3.32). For this we need to perturb the initial data outside of  $B_1(0)$  (see section 4, p 2781-2783 of [CJK2]), to obtain functions  $W_1(x)$  and  $W_2(x)$  which satisfies the followings:

- (a)  $\{W_k > 0\}$  with  $k = 1, 2$  is star-shaped and coincides with  $\Omega_{\alpha r^{-1/2}}(\tilde{w})$  in  $B_{r^{-b}}(0)$ ;
- (b)  $\{W_2 > 0\} \subset \Omega_{\alpha r^{-1/2}}(\tilde{w}) \subset \{W_1 > 0\}$  ;
- (c)  $d(x, \{W_k > 0\}) \geq r^{-b}$  with  $k = 1, 2$  for  $x \in \Gamma_{\alpha r^{-1/2}}(\tilde{w}) \cap (\mathbb{R}^n - B_{2r^{-b}}(0))$ ;
- (d)  $W_k$  is harmonic in  $\{W_k > 0\} - K$  with boundary data zero on  $\Gamma(W_k)$  and  $(1 + r^b)\tilde{w}(x, \alpha r^{-1/2})$  on  $\partial K$ , where

$$K = \{x : d(x, \Gamma(W_k)) \geq r^{-b}\}.$$

Let  $U_k$  be the solution of Hele-Shaw problem in

$$\mathbb{R}^n - \frac{1}{2}\{W_k > 0\} \times [\alpha r^{-1/2}, 1]$$

with initial data  $W_1$  and with lateral boundary data  $(1 + r^b)\tilde{w}(x, \alpha r^{-1/2})$ . Due to Proposition 4.1 of [CJK2], for sufficiently small  $r > 0$ , the level sets of  $U_1$  is then  $\epsilon c$ -close to those of  $U_2$  in  $B_1(0) \times [0, 1]$ . Hence we can use  $U_2$  instead of  $U_1$  in step 4. and proceed as in step 4 to conclude.  $\square$

## 4 Decomposition based on local phase dynamics

Throughout the rest of the paper, let  $u$  be as in Theorem 1.1, and fix  $x_0 \in \Gamma_0$  and a sufficiently small constant  $r > 0$ . We will prove the regularization of the solution  $u$  in  $B_r(x_0) \times [t(x_0, r)/2, t(x_0, r)]$ .

Let us fix a constant  $M \geq M_n$ , where  $M_n$  is a sufficiently large dimensional constant. If the ratio between  $u^+(x_0 - re_n, 0)$  and  $u^-(x_0 + re_n, 0)$  is bigger than  $M$ , then we can directly apply Proposition 3.8 to prove the main theorem. Therefore we assume that

$$M^{-1}u^-(x_0 + re_n, 0) \leq u^+(x_0 - re_n, 0) \leq Mu^-(x_0 + re_n, 0). \quad (4.1)$$

Let

$$C_0 := \max\left\{\frac{u^+(x_0 - re_n, 0)}{r}, \frac{u^-(x_0 + re_n, 0)}{r}\right\}. \quad (4.2)$$

Then since  $u_0^+$  and  $u_0^-$  are comparable with harmonic functions,  $C_0$  is less than a constant depending on  $n$  and  $M$  (See Corollary 2.15). Also note that

$$C_0 \geq r^{\alpha-1} \geq r^{1/6}.$$

Let

$$A^+ = \{x \in \Gamma_0 \cap B_{2r}(x_0) : \frac{u^+(x - se_n, 0)}{s} \geq MC_0 \text{ for some } r^{5/4} \leq s \leq r\}$$

and

$$A^- = \{x \in \Gamma_0 \cap B_{2r}(x_0) : \frac{u^-(x + se_n, 0)}{s} \geq MC_0 \text{ for some } r^{5/4} \leq s \leq r\}.$$

Denote

$$A = A^+ \cup A^-.$$

Throughout the paper we will let  $e_n = x/|x|$  for any boundary point  $x$ , after a necessary rotation.

**Lemma 4.1.** *Let  $u$  be as given in Theorem 1.1, and let  $M$  and  $C$  as given above.*

(a) *If*

$$\frac{u^+(x - se_n, 0)}{s} \geq MC_0 \text{ for some } s \leq r,$$

*then*

$$\frac{u^+(x - se_n, 0)}{s} \leq C_0.$$

(b) *If*

$$\frac{u^-(x + se_n, 0)}{s} \geq MC_0 \text{ for some } s \leq r,$$

*then*

$$\frac{u^-(x + se_n, 0)}{s} \leq C_0.$$

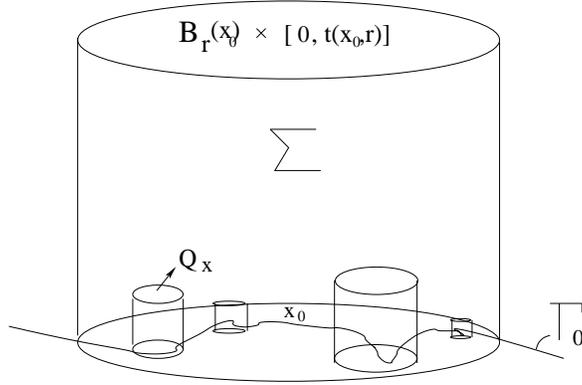

Figure 3: Decomposition of the domain

*Proof.* Since  $u_0^\pm$  are comparable with harmonic functions  $h^\pm$ , we can argue similarly as in Corollary 2.15. Observe

$$\begin{aligned} \frac{u_0^+(x - se_n)}{s} \cdot \frac{u_0^-(x + se_n)}{s} &\sim \frac{h^+(x - se_n)}{s} \cdot \frac{h^-(x + se_n)}{s} \\ &\lesssim \sqrt{\phi(r)} \lesssim C_0^2. \end{aligned}$$

□

Now for  $x \in A^+$ , we can find the largest constant  $r_x < r$  such that

$$\frac{u^+(x - r_x e_n, 0)}{r_x} = MC_0$$

then let

$$Q_x = B_{r_x}(x) \times [0, \frac{r_x}{MC_0}].$$

Also for  $x \in A^-$ , we can similarly define  $r_x$  and  $Q_x$ . Let

$$\Sigma := B_r(x_0) \times [0, t(x_0, r)] - \bigcup_{x \in A} Q_x. \quad (4.3)$$

(See Figure 3)

The following statement is a direct consequence of the definition (4.3).

**Lemma 4.2.** *If  $x \in \Gamma_0 \cap \Sigma_0$ , then for all  $r^{5/4} \leq s \leq r$*

$$\frac{u^+(x - se_n, 0)}{s}, \frac{u^-(x + se_n, 0)}{s} \leq MC_0.$$

The next proposition is the main result in this section, which states that the solution is “well-behaved” in  $\Sigma$ .

**Proposition 4.3.** *There exists a dimensional constant  $K > 0$  such that for all  $(x, t) \in \Gamma \cap \Sigma$*

$$(A) \quad \frac{u^+(x - se_n, t)}{s}, \frac{u^-(x + se_n, t)}{s} < KMC_0 \text{ for } r^{5/4} \leq s \leq r.$$

Before proving Proposition 4.3, we show an immediate consequence of the proposition: we are ready to show that  $\Gamma(u)$  is close to a Lipschitz graph in time as well as in space.

**Corollary 4.4.** *for  $(x, t) \in \Gamma \cap \Sigma$ , suppose  $(x + ke_n, t + \tau) \in \Gamma$ . Then*

$$|k| \leq r^{5/4} \text{ if } \tau \in [0, \frac{r^{5/4}}{K_1MC_0}].$$

where  $K_1$  is a dimensional constant.

*Proof.* Due to Lemma 3.6, at any time  $0 \leq t \leq t(x_0, r)$ , we have

$$h^\pm(x, t) \leq u^\pm(x, t) \leq C_1 h^\pm(x \mp r^{5/4}e_n, t). \quad (4.4)$$

in  $B_r(x_0)$ , where  $h := h^+(\cdot, t) - h^-(\cdot, t)$  is harmonic in its positive and negative phase in  $(1+r)\Omega_t(u) - (1-r)\Omega_t(u)$ , and the domains  $\Omega(h^+)$  and  $\Omega(h^-)$  are both star-shaped with respect to  $B_{r_0}(0)$ . Let us pick  $(y_0, t_0) \in \Gamma \cap \Sigma$ . Due to Proposition 4.3, (4.4) and the Harnack inequality for harmonic functions, we have

$$\sup_{y \in B_{10r^{5/4}}(y_0)} u(y, t_0) \leq CC_1 KMC_0 r^{5/4} \quad (4.5)$$

where  $C$  is a dimensional constant. On the other hand, due to Lemma 3.1 and  $t_0^5 \leq r^{25/6}$ , we have

$$u(\cdot, t_0) \leq 0 \text{ in } B_{\frac{1}{2}r^{5/4}}(y_0 + r^{5/4}e_n). \quad (4.6)$$

Let

$$y_1 := y_0 + r^{5/4}e_n, \quad C_2 := CC_1 KMC_0, \quad r(t) := \frac{1}{2}r^{5/4} - C_3(t - t_0)$$

where  $C_3 = CC_2$ . Next we define  $\phi(x, t)$  in the domain

$$\Pi := B_{2r^{5/4}}(y_1) \times [t_0, t_0 + \frac{r^{5/4}}{C_3}]$$

such that

$$\left\{ \begin{array}{lll} -\Delta \phi(\cdot, t) = 0 & \text{in} & B_{2r^{5/4}}(y_1) - B_{r(t)}(y_1) \\ \phi = 2C_2 r^{5/4} & \text{on} & \partial B_{2r^{5/4}}(y_1) \\ \phi = 0 & \text{in} & B_{r(t)}(y_1). \end{array} \right.$$

Then by (4.4), (4.5) and (4.6),  $u < \phi$  at  $t = t_0$  in  $\Pi$ . Let  $T_0$  be the first time where  $u$  hits  $\phi$  from below in  $\Pi$ . Since (4.5) also holds for any  $(x, t) \in \Gamma \cap \Sigma$  in place of  $(y_0, t_0)$ , we have  $u < \phi$  on the parabolic boundary of  $\Pi \cap \{t_0 \leq t \leq T_0\}$ . On the other hand, if  $C$  is chosen sufficiently large, then

$$\frac{\phi_t}{|D\phi|} = C_3 \geq |D\phi| \text{ on } \partial B_{r(t)}(y_1) \times [t_0, t_1 := t_0 + \frac{r^{5/4}}{4C_3}],$$

and thus  $\phi$  is a supersolution of (ST). This and Theorem 2.11 applied to  $u$  and  $\phi$  in  $\Pi$  yields a contradiction, and we conclude that  $\Gamma(u)$  lies outside of  $B_{\frac{1}{4}r^{5/4}}(y_0 + r^{5/4}e_n)$  for  $t_0 \leq t \leq t_1$ . Similarly, by constructing a negative radial barrier and comparing it with  $u$ , one can show that  $\Gamma(u)$  lies outside of  $B_{\frac{1}{4}r^{5/4}}(y_0 - r^{5/4}e_n)$  for  $t_0 \leq t \leq t_1$ . Hence we conclude.  $\square$

We proceed to show our main result, Proposition 4.3. The following lemmas are used in the proof of the proposition.

- For  $x_0 \in \Gamma_{t_0}$ , define

$$t(x_0, r) := \min\left\{\frac{r^2}{u^+(x_0 - re_n, t_0)}, \frac{r^2}{u^-(x_0 + re_n, t_0)}\right\}.$$

**Lemma 4.5 (Harnack at later times).** *Fix  $s \in [r^{5/4}, r]$ . If  $(y_0, t_0) \in \Gamma \cap \Sigma$ , then*

$$u^+(y_0 - se_n, t_0) \geq c_1 u^+(y_0 - se_n, t_0 + \tau)$$

and

$$u^-(y_0 + se_n, t_0) \geq c_1 u^-(y_0 + se_n, t_0 + \tau)$$

for  $0 \leq \tau \leq t(y_0, s)/2$  and  $c_1 > 0$ .

*Proof.* We will show the lemma for  $u^+$ : the statement on  $u^-$  follows via parallel arguments.

1. Let  $(y_0, t_0) \in \Gamma \cap \Sigma$  and let  $s \in [r^{5/4}, r]$ . Let  $h^+$  be given as in (4.4). Due to Lemma 3.3 and Lemma 3.4, we have

$$\begin{aligned} h^+(y_0 - 2re_n, t_1) &\leq u^+(y_0 - 2re_n, t_1) \\ &\leq C u^+(y_0 - 2re_n, t_2) \leq C h^+(y_0 - (2r + r^{5/4})e_n, t_2) \end{aligned}$$

for  $0 \leq t_1, t_2 \leq t_0 + t(y_0, r)/2$ . (Here note that  $y_0 \in B_r(x_0)$ .) In particular

$$u^+(y_0 - 2re_n, t) \leq C h^+(y_0 - (2r + r^{5/4})e_n, t_0) \leq C_1 h^+(y_0 - 2re_n, t_0) \quad (4.7)$$

for  $t \leq t_0 + t(y_0, s)/2$ .

2. Now let  $v^{**}$  solve (ST1) in  $(\mathbb{R}^n - (1 - 2r)D_{t_0}) \times [t_0, t_0 + t(y_0, s)/2]$  with initial and boundary data  $C_2 h^+(x - 2se_n, t)$ . Since  $s \geq r^{5/4}$ , (4.4) implies

$$\Omega_t(u) \subset \Omega_{t_0}(v^{**}) \subset \Omega_t(v^{**}) \text{ in } B_{2s}(y_0) \times [t_0, t_0 + t(y_0, s)/2]. \quad (4.8)$$

Then by (4.8), (4.7) and (4.4),

$$u^+ \leq v^{**} \text{ in } B_s(y_0) \times [t_0, t_0 + t(y_0, s)/2]$$

if we choose  $C_2$  as a multiple of  $C_1$  by a dimensional constant. Moreover, due to the Harnack inequality for one-phase (ST1), one can conclude that

$$\begin{aligned} u^+(y_0 - se_n, t_0 + \tau) &\leq v^{**}(y_0 - se_n, t_0 + \tau) \\ &\leq C v^{**}(y_0 - se_n, t_0) \\ &= C C_2 h^+(y_0 - 3se_n, t_0) \\ &\leq C_3 h^+(y_0 - se_n, t_0) \\ &\leq C_3 u^+(y_0 - se_n, t_0) \end{aligned}$$

for  $0 \leq \tau \leq \frac{s^2}{v^{**}(y_0 - se_n, t_0)} \sim t(y_0, s)/2$ . Here the first inequality uses  $u^+ \leq v^{**}$ , the second uses the Harnack inequality for  $v^{**}$ , the third one uses the Harnack inequality for harmonic functions and the last one uses (4.4).  $\square$

**Lemma 4.6 (Backward harnack).** *Suppose that (A) holds up to time  $t = T_0 \leq t(x_0, r)$ . If  $(y_0, t_0) \in \Gamma$  and  $t_0 \leq T_0$ , then for  $0 \leq \tau \leq t(y_0, s)/2$ ,*

$$u^+(y_0 - se_n, t_0) \leq C u^+(y_0 - se_n, t_0 + \tau)$$

and

$$u^-(y_0 + se_n, t_0) \leq C u^-(y_0 + se_n, t_0 + \tau)$$

where  $0 \leq s \leq r$  and  $C$  is a universal constant.

*Proof.* We will show the argument for  $u^+$ , due to the symmetric nature of the claim. The argument here will be similar to that of Lemma 3.4, replacing the initial data  $u_0^+$  and  $u_0^-$  (used in the construction of barriers) by  $h^+(x, t_0)$  and  $h^-(x, t_0)$  given in (4.4).

We consider  $v_1$ : a one-phase solution of (ST1) in

$$\Pi := (1 + r)\Omega_{t_0} \times [t_0, t_0 + t(y_0, s)/2]$$

with initial and lateral boundary data  $C_1 h^-$ . Then  $v_1 \leq u$  in  $\Pi$ . Now let  $v_2$  solve the heat equation in  $\{v_1 = 0\} \times [t_0, t_0 + t(y_0, s)/2]$  with initial data

$$v_2(\cdot, t_0) = \begin{cases} h^+(\cdot, t_0) & \text{in } \{v_1(\cdot, t_0) = 0\} - (1 - r)\{h^+(\cdot, t_0) > 0\} \\ \tilde{h}(\cdot) & \text{in } (1 - r)\{h^+(\cdot, t_0) > 0\}, \end{cases}$$

where  $\tilde{h}(\cdot)$  is a  $C^2$  extension function of  $h^+(\cdot, t_0)$  chosen so that  $\tilde{h}(\cdot) \leq u^+(\cdot, t_0)$ . The rest of the proof is the same as that of Lemma 3.4.  $\square$

**Lemma 4.7. (Regularization in unbalanced region II)** *For a fixed  $(x_0, t_0) \in \Gamma(u)$ , and suppose*

$$u^+(x_0 - re_n, t_0) \geq Mu^-(x_0 + re_n, t_0)$$

or

$$u^-(x_0 + re_n, t_0) \geq Mu^+(x_0 - re_n, t_0)$$

for  $M > M_n$ , where  $M_n$  is a dimensional constant. Then for  $r \leq 1/M_n$ , there exists a dimensional constant  $C > 0$  such that

$$|Du^+| \leq C \frac{u^+(x_0 - re_n, t_0)}{r} \quad \text{and} \quad |Du^-| \leq C \frac{u^-(x_0 + re_n, t_0)}{r}$$

in  $B_r(x_0) \times [t_0 + t(x_0, r)/2, t_0 + t(x_0, r)]$ .

*Proof.* The proof of this lemma is parallel to that of Proposition 3.8. We use Harnack and backward Harnack inequalities (Lemmas 4.5 and 4.6) instead of Lemmas 3.3 and 3.4. Also we have Lemma 3.6.  $\square$

We are now ready to prove our main result, Proposition 4.3. Observe that (A) holds up to some  $T_0 > 0$  by Lemma 4.2 and Lemma 3.3.

*Proof of Proposition 4.3.* Let  $K$  be a sufficiently large dimensional constant such that  $K \gg M$ . Let us assume that (A) breaks down for  $u^+$  for the first time at  $t = T_0$ . Then

$$\frac{u^+(z_0 - se_n, T_0)}{s} = KMC_0 \tag{4.9}$$

for some  $(z_0, T_0) \in \Gamma \cap \Sigma$  and  $r^{5/4} \leq s \leq r$ . Let

$$h = \sup\{h : \frac{u^+(z_0 - ke_n, T_0)}{k} \geq M^2C_0 \text{ for } s \leq k \leq h\}. \tag{4.10}$$

Note that  $h < r/2$  due to Lemma 3.3 and the definition of  $C_0$ , and  $h > 2s$  due to Lemma 3.6. By the definition of  $h$  we have

$$\frac{u^+(z_0 - he_n, T_0)}{h} = M^2C_0. \tag{4.11}$$

Let us find  $t_0$ : the closest time before  $T_0$  such that for some  $(y_0, t_0) \in \Gamma$

$$T_0 - t_0 = t(y_0, h)/2 \quad \text{and} \quad y_0/|y_0| = z_0/|z_0|.$$

Then Lemma 4.5 implies

$$\frac{u^+(y_0 - he_n, t_0)}{h} \sim \frac{u^+(y_0 - he_n, T_0)}{h} \sim \frac{u^+(z_0 - he_n, T_0)}{h} = M^2C_0.$$

Since  $u^+(\cdot, t_0)$  and  $u^-(\cdot, t_0)$  are comparable to harmonic functions (Lemma 3.6), a similar argument as in Lemma 4.1 implies that

$$\frac{u^-(y_0 + he_n, t_0)}{h} \lesssim C_0 \lesssim \frac{1}{M^2} \frac{u^+(y_0 - he_n, t_0)}{h}.$$

Hence by Lemma 4.7, we have

$$|Du^+(\cdot, T_0)| \sim M^2 C_0 \text{ in } B_h(y_0)$$

Since  $B_s(z_0) \subset B_h(y_0)$ , this would contradict (4.9) since  $K \gg M$ .  $\square$

Due to Lemma 3.6, Proposition 4.3 and Corollary 4.4, we have shown (A) and that the level sets of  $u$  are close to a Lipschitz graph, and  $\Gamma(u)$  is close to a Lipschitz graph in space and time. (see detailed description of this fact in the next section). On the other hand we do not yet have sufficient control for the change of  $u$  over time to verify the condition (B'). We will therefore prove Theorem 1.1 by carrying out a modified argument, combining arguments from [ACS1]-[ACS2] and [CJK1]-[CJK2].

## 5 Further regularization based on Flatness

Recall that  $x_0 \in \Gamma_0$  and  $r > 0$  are fixed, and they satisfy (4.1). Let  $C_0$  as given in (4.2).

Our goal is to prove the regularization of the free boundary after the time  $t(x_0, r)/2$  in  $B_r(x_0)$ . Define

$$Q_r(x_0) := B_r(x_0) \times [t(x_0, r)/2, t(x_0, r)] \subset \Sigma.$$

Let us briefly review the information we have on  $u$  so far. As a result of Proposition 4.3, (A) holds up to

$$t = t(x_0, r) \leq Cr^{2-\alpha} < r^{3/4}.$$

Also due to Lemma 3.6, our solution  $u$  is  $\epsilon$ -monotone in  $Q_r(x_0)$ , with respect to the space cone  $W_x(e_n, \theta_0)$  satisfies

$$|\theta_0 - \pi| = O(L)$$

where  $L$  is the Lipschitz constant of the initial domain  $\Omega_0$  given by (1.1).

Moreover  $Q_r(x_0) \subset \Sigma$ , and thus Corollary 4.4 and Lemma 3.1, the free boundary  $\Gamma(u)$  is  $r^{4/3}$ -monotone in  $Q_r(x_0)$  with respect to the time cone  $W_t(e_n, \tan^{-1}(1/K_1 M C_0))$  and the space cone  $W_x(e_n, \theta_0)$ . Here  $\theta_0$  is the angle corresponding to the Lipschitz constant of  $\Gamma_0$ , and  $t(x_0, r) = \frac{r}{C_0}$ .

On the other hand, by Lemma 3.3 and the definition of  $C_0$ ,

$$\frac{u(x_0 - re_n, \frac{t(x_0, r)}{2})}{C_0 r} \sim 1.$$

Since  $Q_r(x_0) \subset \Sigma$ , Proposition 4.3 implies

$$\frac{u(x, t)}{C_0 r} \lesssim KM \text{ in } B_r(x_0) \times [t(x_0, r)/2, t(x_0, r)].$$

The main difficulty in applying the method of [ACS1]-[ACS2] lies in the fact that we cannot guarantee the  $\epsilon$ -monotonicity of the solution  $u$  in time variable (although we can obtain, as above, the  $r^{4/3}$ -monotonicity of the free boundary  $\Gamma(u)$ ). To go around this difficulty, we will first use the parabolic scale to improve the regularity of the solution in space. Consider the function

$$\bar{u}(x, t) := \frac{1}{C_0 r} u(rx + x_0, r^2 t + \frac{t(x_0, r)}{2}).$$

In [ACS1]-[ACS2], it was important that initially the time derivative of the solution was assumed to be controlled by the spatial derivative, i.e.,

$$|u_t| \leq C(|Du^+| + |Du^-|). \quad (5.1)$$

Using (5.1) one can prove that the *direction vectors*

$$\frac{Du^+}{|Du^+|}(-le_n, t), \quad \frac{Du^-}{|Du^-|}(le_n, t)$$

do not change much for  $0 \leq t \leq l$ . This is pivotal in regularization procedure since then  $\Gamma(u)$  regularizes along the direction of the “common gain” obtained by those two direction vectors, the regularity of  $\Gamma(u)$  then makes above two vectors line up better in a smaller scale, which contributes to further regularization of  $\Gamma(u)$  in a finer scale. In our case we do not have (5.1), which requires an extra care in showing that the vectors do not change their directions too rapidly.

◦ *Lipschitz continuity in space*

First we prove that the  $\epsilon$ -monotonicity of  $\Gamma(\bar{u})$  improves to Lipschitz continuity. Let  $a = C_0 r$ . Then in the domain  $B_1(0) \times [-\frac{1}{a}, \frac{1}{a}]$ ,  $\bar{u}(x, t)$  solves

$$\begin{cases} \bar{u}_t - \Delta \bar{u} = 0 & \text{in } \{\bar{u} > 0\} \\ V = a(|D\bar{u}^+| - |D\bar{u}^-|) & \text{on } \partial\{\bar{u} > 0\}. \end{cases}$$

Here note that

$$r^{7/6} \leq r^\alpha \leq a \leq r^\beta \leq r^{5/6}.$$

In this scale, since  $\bar{u}$  is Caloric and  $\Gamma(\bar{u})$  is  $r^{1/3}$ -close to a Lipschitz graph in space and time, it follows that so does  $\bar{u}$  in  $B_{1/2}(0) \times [-\frac{1}{a} + 1, \frac{1}{a}]$ .

Note that in above step we are losing a lot of information over time:  $\Gamma(\bar{u})$  is in fact  $r^{1/3}$ -close to a Lipschitz graph moving very slow in time, but this does not guarantee that  $\bar{u}$  also changes slowly in time.

We then follow the iteration process in Lemma 7.2 of [ACS] to show the following:

**Lemma 5.1.** *If  $r$  is sufficiently small, then there exists  $0 < c, d < 1/2$  such that the following is true:  $\bar{u}$  is  $\lambda r^{1/3}$ -monotone in the cone of directions  $W_x(\theta_x - r^d, e_n)$  and  $W_t(\theta_t - r^d, \nu)$  in the domain  $B_{1-r^c}(0) \times [\frac{-1+r^c}{a}, \frac{1}{a}]$ .*

One can then iterate above lemma to improve the  $\epsilon$ -monotonicity to full monotonicity, and state the result in terms of  $\bar{u}$ :

**Lemma 5.2.**  *$\bar{u}$  is fully monotone in  $B_{1/2}(0) \times [0, \frac{1}{a}]$  for the cone*

$$\mathcal{C}_1 := W_x(\theta_x - r^d, e_n) \cup W_t(\theta_t - r^d, \nu),$$

for some constant  $0 < d < 1/2$ .

◦ *Regularity in time away from the free boundary*

Now we suppose  $\bar{u}$  is Lipschitz in space and time. Then in particular, we have the Lipschitz regularity of  $u$  in space (and very weak Lipschitz regularity of  $u$  in time.) We are interested in proving the following type of statement:

**Lemma 5.3** (Enlargement for the cone of monotonicity). *There exists  $\lambda > 0$  such that the following holds: Suppose  $\bar{u}$  is Lipschitz with respect to the cone of monotonicity  $\Lambda_x(e_n, \theta_0)$  in  $B_1(0) \times [-\frac{1}{a}, \frac{1}{a}]$ . Then in the half domain  $B_{1/2}(0) \times [-\frac{1}{2a}, \frac{1}{2a}]$ ,  $\bar{u}$  is Lipschitz with respect to the cone of monotonicity  $\Lambda_x(\nu, (1+\lambda)\theta_0)$  with some unit vector  $\nu$ .*

To prove the enlargement of the cone, we take a closer look at the change of  $\bar{u}$  over time, in the interior region. More precisely, we need the following lemma which follows the approach taken in [CJK1] and [CJK2].

**Lemma 5.4.**

$$|\bar{u}_t| \leq a|D\bar{u}|^2 \leq Ca \text{ in } [B_{1/2}(e_n) \cup B_{1/2}(-e_n)] \times [-1/2a, 1/2a],$$

where  $C$  is a dimensional constant.

*Proof.* 1. The proof is similar to that of Lemma 8.3 of [CJK2]. Note that  $\bar{u}_t$  is a caloric function in  $\Omega^+(\bar{u})$  and  $\Omega^-(\bar{u})$ . Let us prove the lemma for  $\bar{u}^+$ , since parallel arguments apply to  $\bar{u}^-$ .

2. We divide  $\bar{u}_t$  into two parts. More precisely, let

$$\bar{u}_t = v_1 + v_2,$$

where both  $v_1$  and  $v_2$  are caloric in  $\Omega^+(\bar{u})$ ,  $v_1$  has initial data zero and the boundary data  $a|D\bar{u}^+|(|D\bar{u}^+| - |D\bar{u}^-|)$  on  $\Gamma(\bar{u})$ , and  $v_2$  has the initial data  $\bar{u}_t(\cdot, -1/a)$  and the boundary data zero on  $\Gamma(\bar{u})$ .

3. As for  $v_1$ , we need to use the absolute continuity of the caloric measure with respect to the harmonic measure, as well as the Lipschitz continuity of the free boundary. we proceed as in Lemma 8.3 of [CJK1]. Note that we have

$$|D\bar{u}^+| \sim |D\bar{u}^-| \sim 1$$

in  $[B_{1/2}(e_n) \cup B_{1/2}(-e_n)] \times [-1/a, 1/a]$ : this follows from the assumption (4.1), and Lemmas 3.3 and 3.4. Therefore we can proceed as in Lemma 8.3 of [CJK1] to obtain

$$v_1(x, t) \leq a \int_{\Gamma(\bar{u}) \cap \{-1/a \leq s \leq t\}} |D\bar{u}^+|^2 d\omega^{(x, t)} \leq a |D\bar{u}|^2(x, t)$$

where  $\omega^{(x, t)}$  is the caloric measure for  $\Omega(\bar{u})$ .

$$v_1(x, t) \geq a \int_{\Gamma(\bar{u}) \cap \{-1/a \leq s \leq t\}} -|D\bar{u}^-|^2 d\omega^{(x, t)} \geq -a |D\bar{u}|^2(x, t).$$

4. As for  $v_2$ , we conclude that it must be smaller than that of caloric function solved in the whole domain with the absolute value of its initial data. The advantage is that then we can use the heat kernel. Note that the initial data is given at  $t = -1/a$  and has a compact support. The initial data is given by  $v_t \leq \frac{C}{a} v_{e_n}$ , where  $v_{e_n}(x, t)$  is comparable to the derivative of harmonic function in Lipschitz domain.

Therefore the heat kernel representation is given as

$$\frac{1}{(t + 1/a)^{\frac{n}{2} + 1}} \int |x_n - y_n| \exp^{-|x-y|^2/(t+1/a)} v(y, -1/a) dy.$$

Since  $t \in [0, 1/a]$ , and  $k \exp^{-ak^2} \leq C \exp^{-\frac{a}{2}k^2}$ , we get the effect of  $O(a)$ .  $\square$

◦ *Further regularity in space*

Now that we have sufficient information on the change of  $u$  over time, we change the scale following the one introduced in (1.4), and consider the function

$$v(x, t) := \frac{1}{C_0 r} u(rx + x_0, \frac{r}{C_0} t + 1) \quad (5.2)$$

Note that  $C_0 = r^{-1} c(x_0, r)$ , and thus  $v$  coincides with  $\tilde{u}$  defined in (1.4) with the choice of  $c = rC_0$ .

Due to the previous results, this function is Lipschitz continuous, in space and time, *away* from the free boundary. The following lemma suggests that the cone of monotonicity improves away from the free boundary, as we look at smaller scales. The proof is parallel to that of Lemma 8.4 in [ACS2].

**Lemma 5.5.** *Let  $v$  given by (5.2). Suppose that there exists constants  $\delta > 0$  and  $0 \leq A \leq B, \mu := B - A$  such that*

$$\alpha(Dv, -e_n) \leq \delta \text{ and } A \leq \frac{v_t}{-e_n \cdot Dv} \leq B$$

*in  $B_{1/6}(-\frac{3}{4}e_n) \times (-\delta/\mu, \delta/\mu)$  with  $\frac{\delta}{\mu} < r$ . Then there exist a unit vector  $\nu \in \mathbb{R}^n$  and positive constants  $r_0, b_0 < 1$  depending only on  $A, B$  and  $n$  such that*

$$\alpha(Dv(x, t), \nu) \leq b_0 \delta \text{ in } B_{1/8}(-\frac{3}{4}e_n) \times (-r_0 \frac{\delta}{\mu}, r_0 \frac{\delta}{\mu}).$$

Now we can proceed as in section 6 of [CJK2] to obtain further regularity, using Lemma 5.4 instead of the uniform upper bound on  $|Du|$  up to the free boundary.

**Theorem 5.6.**  $\Gamma(v)$  is  $C^1$  in space in  $Q_{1/2}$ . In particular, there exist constants  $l_0, C_0 > 0$  depending only on  $L, n$  and  $M$  such that for a free boundary point  $(x_0, t_0) \in \Gamma(v)$ ,  $\Gamma(v) \cap (B_{2^{-l}}(x_0) \times [t_0 - 2^{-l}, t_0 + 2^{-l}])$  is a Lipschitz graph in space with Lipschitz constant less than  $\frac{C_0}{l}$  if  $l \geq l_0$ .

◦ *Regularity in time up to the free boundary*

Lastly, proceeding as in section 7-8 of [CJK2] yields the differentiability of  $\Gamma(v)$  in time. The main step in the argument is the following proposition: the statement and its proof is parallel to those of Theorem 7.2 in [CJK2] and the blow-up argument as in section 8 of [CJK2]:

**Theorem 5.7.**  $\Gamma(v)$  is differentiable in space and time. More precisely there exist constants  $l_0 > 0$  and  $1 < \gamma < 2$  depending only on  $L, n, M$  such that for  $(x_0, t_0) \in \Gamma(v) \cap Q_1$ , if  $l > l_0$  then  $\Gamma(v) \cap (B_{2^{-l}}(x_0) \times [t_0 - 2^{-l}, t_0 + 2^{-l}])$  is a Lipschitz graph in space with Lipschitz constant less than  $l^{-\gamma}$ , and Lipschitz graph in time with Lipschitz constant less than  $l^{-1/3}$ .

**Corollary 5.8.**

$$C^{-1} \leq |Dv^+|(x, t) \leq C, \quad C^{-1} \leq \frac{|Dv^-|(x, t)}{v(-e_n, t)} \leq C$$

in  $Q_{1/2}$ , where  $C = C(M, n)$ .

## 6 General case: solutions with Locally Lipschitz Initial data

In this section, we present how to extend the result of the main theorem to solutions with locally Lipschitz initial data. Our setting is as follows. Suppose  $\Omega_0$  is a bounded region in  $B_R(0)$ . Suppose  $u$  is a solution of (ST2) with  $u_0 \geq -1$ ,  $u_0 = -1$  on  $B_R(0)$  and  $u_0 \leq M_0$ . Further suppose that  $\Omega_0$  is locally Lipschitz: that is, for any  $x_0 \in \Gamma_0$ ,  $\Gamma_0 \cap B_1(x_0)$  is Lipschitz with a Lipschitz constant  $L \leq L_n$ .

Let the initial data  $u_0$  solve  $\Delta u_0 = 0$  in  $B_1(x_0)$ . Then we claim that the parallel statements as in Theorem 1.1 hold in  $B_{2d_0}(x_0) \times [t(x_0, d_0)/2, t(x_0, d_0)]$ , where  $d_0$  is a constant depending on  $n$  and  $M_0$ . More precisely:

**Theorem 6.1.** *Suppose  $u$  is a solution of (ST2) with initial data  $u_0$  such that  $-1 \leq u_0 \leq M_0$ . Further suppose that for  $x_0 \in \Gamma_0$ ,  $\Gamma_0 \cap B_1(x_0)$  is Lipschitz with a Lipschitz constant  $L \leq L_n$  and  $\Delta u_0 = 0$  in the positive and negative phases of  $u_0$  in  $B_1(x_0)$ . Then there exists a constant  $d_0 > 0$  depending on  $n$  and  $M_0$  such that (a) and (b) of Theorem 1.1 hold for  $u$  and  $d \leq d_0$ .*

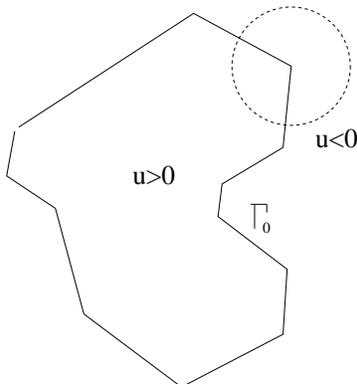

Figure 4: Locally Lipschitz initial domain

The proof of the above theorem is parallel to that of Theorem 1.1 in section 5, after proving the following lemma.

**Lemma 6.2.** *There exists a solution  $v$  of (ST2) with a star-shaped initial data such that the level sets of  $u$  and  $v$  are  $\epsilon d_0$ -close to each other in  $B_{2d_0}(x_0)$  up to the time  $t(x_0, d_0; u)$ , where  $d_0 > 0$  is sufficiently small. In particular,  $u$  and  $\Gamma(u)$  is  $\epsilon$ -monotone in a cone of  $W_x$  and  $W_t$  in  $B_{2d_0}(x_0) \times [t(x_0, d_0)/2, t(x_0, d_0)]$ .*

Even though our equation is nonlocal, the behavior of far-away region would not affect much the behavior of solution in the unit ball, if the solution behaves “reasonably” outside the unit ball. For example, in the star-shaped case, we know at least that the free boundary is almost locally Lipschitz at each time. In the locally Lipschitz case, we control the solution by putting an upper bound  $M_0$  on the initial data  $u_0$ . We will argue that in a sufficiently small subregion of  $B_1(x_0) \times [0, 1]$ , the solution is mostly determined by the local initial data in  $B_1(x_0)$ . The perturbation method in the proof of Lemma 2.4 in [CJK1] will be adopted here. Denote  $B_1(x_0) = B_1$ .

1. Construct a star-shaped region  $\Omega' \subset B_R(0)$  such that

- (a)  $\Omega' \cap B_1 = \Omega_0 \cap B_1$ .
- (b)  $\Omega'$  is star-shaped with respect to every  $x \in K \subset \Omega'$  for a sufficiently large ball  $K$ .

Let  $v_0^+$  be the harmonic function in  $\Omega' - K$  with boundary data 1 on  $\partial K$ , and 0 on  $\partial\Omega'$ . Next, let  $v_0^-$  be the harmonic function in  $B_R(0) - \Omega'$  with boundary data 1 on  $\partial B_R(0)$ , and 0 on  $\partial\Omega'$ . Let  $B_2$  be a concentric ball in  $B_1$  with the radius of  $\epsilon^{k_0}$ , i.e.,

$$B_2 = B_{\epsilon^{k_0}}(x_0) \subset B_1(x_0) = B_1.$$

Let  $k_0$  be sufficiently large. Then by Lemma 2.7, a normalization of  $v_0^\pm$  by a

suitable constant multiple yields that for any  $x \in B_2$

$$1 - \epsilon \leq \frac{u_0(x)}{v_0(x)} \leq 1 + \epsilon. \quad (6.1)$$

Let  $v$  solve (ST2) with initial data  $v_0 = v_0^+ - v_0^-$ . Then Theorem 1.1 applies for  $v$  since  $v_0$  is star-shaped with respect to  $K$ .

For the proof of the claim, we will find a sufficiently small  $d_0$  such that  $v$  is  $\epsilon d_0$ -close to  $u$  in  $B_{2d_0}(x_0)$  up to the time  $t(x_0, d_0)$ . More precisely, we will construct a supersolution  $w_1$  and a subsolution  $w_2$  of (ST2) such that in some small ball  $B_h(x_0)$ , we have

$$w_2 \leq u \leq w_1$$

and the level sets of  $w_1$  and  $w_2$  are  $h\epsilon$  close to the level sets of  $v$ .

2. Let  $k_1$  and  $k_2$  be large constants which will be determined later. Define

$$H^\pm := (\Gamma_0(v) \pm \epsilon^{k_0+k_1} e_n) \cap B_2.$$

Let

$$d_0 := \epsilon^{k_0+k_1+k_2}.$$

and let  $t(d_0) := t(x_0, d_0; v) = t(x_0, d_0; u)$ . First note that

$$t(d_0) \geq d_0^{2-\beta} \geq \epsilon^{7(k_0+k_1+k_2)/6}.$$

Hence for  $v$  to be almost harmonic in a scale much larger than  $\epsilon^{k_0+k_1}$ , we need  $\sqrt{t(d_0)} > \epsilon^{k_0}$ , i.e.,

$$7(k_0 + k_1 + k_2)/12 < k_0.$$

Observe that by the construction of  $H^\pm$  and  $d_0$ ,

$$\sqrt{t(d_0)} \gg \text{radius}(B_2) \gg \text{dist}(H^\pm, \Gamma_0) \gg \max_{x \in \Gamma_t \cap B_2, 0 \leq t \leq t(d_0)} \text{dist}(x, \Gamma_0) \quad (6.2)$$

where the last inequality follows from Lemma 2.12 if we choose  $k_2 \geq 2k_1$ . If  $k_2$  is sufficiently large, then one can prove from the last inequality of (6.2) and the bound on  $v_t$  that

$$1 - \epsilon \leq \frac{|v(x, t)|}{|v_0(x)|} = \frac{|v(x, t)|}{|u_0(x)|} \leq 1 + \epsilon \text{ on } H^\pm \times [0, t(d_0)]. \quad (6.3)$$

3. We do have an estimate, Lemma 2.12, on how far the boundaries move away for the local one-phase case. If we take the one-phase versions with initial data  $u_0^+$  and  $u_0^-$ , and compare with  $u$ , then we obtain that  $\Gamma(u) \cap B_2$  stays in the  $d_0^{\frac{2-\alpha}{2-\beta}}$ -neighborhood of  $\Gamma_0(u) \cap B_2$  up to the time  $t(d_0) = t(x_0, d_0)$ . In other words, the free boundary of  $u$  moves less than  $d_0^{5/7}$  in  $B_2$  up to the time  $t(d_0)$ .

Now we let  $S$  be the region between  $H^+$  and  $H^-$ . To construct a sub (or super) solution in  $S$ , we take the fixed boundary data  $(1 - \epsilon)v_0(x)$  on  $H^-$  (or

$H^+$ ), and  $(1 + \epsilon)v_0(x)$  on  $H^+$  (or  $H^-$ ). To control the effect from the side  $\partial B_2 \cap S$ , we bend the free boundary  $\Gamma_t(v)$  by  $d_0^{5/7}$  on each side of  $\partial B_2 \cap S$ , using the conformal mapping  $\hat{\Phi}$  (or  $\check{\Phi}$ ). (See section 4 of for the definition of  $\hat{\Phi}$  and  $\check{\Phi}$ .) More precisely, we bend the free boundary of  $v$  downward (or upward) using the conformal map  $\hat{\Phi}$  (or  $\check{\Phi}$ ), and solve the heat equation in there. Then similar arguments as in Lemmas 4.1 and 4.3 of [CK] yield that the solution is still (almost) a supersolution, and it stays close to the original solution.
