# The method of partial fractions

- The purpose of the **method of partial fractions** is to find antiderivatives of **rational functions**, i.e. functions of the form  $f(x) = \frac{P(x)}{Q(x)}$ , where  $P$  and  $Q$  are polynomials.

- The method involves **three steps**:

- If  $d^\circ(P) \geq d^\circ(Q)$ , first **use long-division** and re-write  $f$  as

$$f(x) = N(x) + \frac{H(x)}{Q(x)}, \quad d^\circ(H) < d^\circ(Q),$$

where  $N$  and  $H$  are polynomials. Then, apply the method to the rational function  $H(x)/Q(x)$ .

- If  $d^\circ(P) < d^\circ(Q)$ , find the **partial fraction decomposition** of  $P(x)/Q(x)$ .
- Integrate** each of the terms appearing in the partial fraction decomposition of  $f$  to obtain an antiderivative of  $f$ .

Methods of integration II

Calculus and Differential Equations I

# The method of partial fractions (continued)

- To do this, we need to be able to perform each of the steps separately. They are:

- Long-division** of polynomials
- Partial fraction decomposition** of  $P(x)/Q(x)$  where  $d^\circ(P) < d^\circ(Q)$
- Integration** of terms that typically appear in a decomposition into partial fractions. Such terms are of the form

$$\frac{A}{(x-a)^n} \quad \text{and} \quad \frac{Bx+C}{(x^2+bx+c)^n},$$

where  $n \geq 1$  and  $x^2 + bx + c$  is **irreducible**.

- Example for step 1:** Divide  $x^3$  by  $x^2 + 3x + 2$ .

Methods of integration II

Calculus and Differential Equations I

# Examples of application

- We have already used partial fractions when solving the **logistic equation**.

- Solve the following differential equation

$$\frac{dy}{dx} = \frac{(y+1)(y^2 - 2y + 3)}{y^2 + 5}.$$

- Solve the differential equation

$$\frac{dy}{dx} = \frac{(y-1)^3}{y^4}$$

with the following initial conditions

- $y(0) = 2$
- $y(0) = 1$

Methods of integration II

Calculus and Differential Equations I

## Trigonometric substitutions

**Trigonometric substitutions** take advantage of known algebraic relationship between

- **Sines, cosines, and tangents**

$$\begin{aligned}\cos^2(\theta) + \sin^2(\theta) &= 1 \\ \frac{d}{d\theta} \cos(\theta) &= -\sin(\theta) & \frac{d}{d\theta} \sin(\theta) &= \cos(\theta) \\ \frac{d}{d\theta} \tan(\theta) &= 1 + \tan^2(\theta) = \frac{1}{\cos^2(\theta)}\end{aligned}$$

- **Hyperbolic sines, cosines and tangents**

$$\begin{aligned}\cosh^2(\theta) - \sinh^2(\theta) &= 1 \\ \frac{d}{d\theta} \cosh(\theta) &= \sinh(\theta) & \frac{d}{d\theta} \sinh(\theta) &= \cosh(\theta) \\ \frac{d}{d\theta} \tanh(\theta) &= 1 - \tanh^2(\theta) = \frac{1}{\cosh^2(\theta)}\end{aligned}$$

## Trigonometric substitutions (continued)

- For integrands that involve  $\sqrt{a^2 - x^2}$ ,  $a > 0$ , note that  $|x| \leq a$ , and try the substitution  $x = a \sin(\theta)$ .
- Since the integrand will involve  $\sqrt{\cos^2(\theta)}$  and the  $dx$  will be given by  $dx = a \cos(\theta) d\theta$ , one can expect to be able to simplify the integral after such a substitution.
- **Example:** Show that  $\int \frac{dx}{\sqrt{a^2 - x^2}} = \arcsin\left(\frac{x}{a}\right) + C$ .
- Similarly, for integrands that involve  $\sqrt{x^2 - a^2}$ ,  $a > 0$ , one can change variables so that  $x > 0$  and then try  $x = a \cosh(\theta)$  since  $x^2 \geq a^2$ .
- **Examples:** Show that  $\int \sqrt{x^2 - a^2} dx$  can be written as  $a^2 \int \sinh^2(\theta) d\theta$  after a substitution.

## Half-angle substitutions

- **Half-angle substitutions** are useful to find antiderivatives of products and/or ratios of sines and cosines.

- Indeed, let  $t = \tan(\theta/2)$ . Then,

$$\cos(\theta) = \frac{1 - t^2}{1 + t^2}, \quad \sin(\theta) = \frac{2t}{1 + t^2}, \quad dt = \frac{1}{2}(1 + t^2) d\theta.$$

- A product or ratio of sines and cosines will thus be transformed into a **rational function** of  $t$ , which we know how to integrate (using partial fractions).

- **Example:** Show that  $\int \frac{d\theta}{\sin(\theta)} = \ln \left| \tan\left(\frac{\theta}{2}\right) \right| + C$ .

## Partial fraction decomposition

To decompose the rational function  $\frac{P(x)}{Q(x)}$  where  $d^\circ(P) < d^\circ(Q)$ , into **partial fractions**, proceed as follows.

- 1 **Factor the denominator**  $Q(x)$  into terms of the form  $(x - a)^n$  and  $(x^2 + bx + c)^n$ , where  $n \geq 1$  and  $x^2 + bx + c$  is **irreducible**.
- 2 For each factor of the form  $(x - a)^n$ , the partial fraction decomposition of  $P(x)/Q(x)$  will include terms of the form

$$\frac{A_1}{x - a}, \frac{A_2}{(x - a)^2}, \dots, \frac{A_j}{(x - a)^j}, \dots, \frac{A_n}{(x - a)^n}.$$

- 3 **To find  $A_n$** , multiply by  $(x - a)^n$  and set  $x = a$  into the resulting equation.
- 4 **To find the  $A_j$ 's,  $j \neq n$** , multiply by  $(x - a)^n$ , and substitute in appropriate values of  $x$ .

## Partial fraction decomposition (continued)

- 5 For each factor of the form  $(x^2 + bx + c)^n$ , the partial fraction decomposition of  $P(x)/Q(x)$  will include terms of the form

$$\frac{B_1x + C_1}{x^2 + bx + c}, \dots, \frac{B_jx + C_j}{(x^2 + bx + c)^j}, \dots, \frac{B_nx + C_n}{(x^2 + bx + c)^n}.$$

- 6 To find the  $B_j$ 's and  $C_j$ 's, multiply by  $(x^2 + bx + c)^n$ , expand, and equate the coefficients of the various powers of  $x$  in both sides of the resulting equation.

**Example:** Find the partial fraction decomposition of

$$f(x) = \frac{x^2 + 5}{(x + 1)(x^2 - 2x + 3)}.$$

## Integration of a partial fraction decomposition

Typical terms in a partial fraction decomposition are of the form

$$\frac{A}{(x - a)^n} \quad \text{and} \quad \frac{Bx + C}{(x^2 + bx + c)^n}.$$

- 1 Terms of the form  $\frac{A}{(x - a)^n}$ ,  $n \geq 1$

- If  $n = 1$ , then

$$\int \frac{A}{x - a} dx = \ln(|x - a|) + C.$$

- If  $n > 1$ , then

$$\int \frac{A}{(x - a)^n} dx = \frac{-A}{n - 1} \frac{1}{(x - a)^{n-1}} + C.$$

## Integration of a partial fraction decomposition (continued)

- 2 Terms of the form  $\frac{Bx + C}{(x^2 + bx + c)^n}$ ,  $n \geq 1$

- 1 Compare the numerator to the derivative of  $x^2 + bx + c$ .

$$\begin{aligned} \int \frac{Bx + C}{(x^2 + bx + c)^n} dx &= \int \frac{\frac{B}{2}(2x + b) - \frac{bB}{2} + C}{(x^2 + bx + c)^n} dx \\ &= \frac{B}{2} \int \frac{du}{u^n} + D \int \frac{dx}{(x^2 + bx + c)^n}, \end{aligned}$$

where  $u = x^2 + bx + c$  and  $D = C - \frac{bB}{2}$ .

- 2 Thus, we can integrate provided we know how to find an antiderivative of  $1/(x^2 + bx + c)^n$ .

- 3 Note that since  $x^2 + bx + c$  is **irreducible**, one can write  $x^2 + bx + c = \left(x + \frac{b}{2}\right)^2 + d^2$ , where  $d^2 = c - \frac{b^2}{4}$ .

## Integration of a partial fraction decomposition (continued)

- 3 To integrate  $\frac{1}{\left(x + \frac{b}{2}\right)^2 + d^2}^n$ , let  $u = \frac{x}{d} + \frac{b}{2d}$ . Then,

$$\int \frac{dx}{\left(x + \frac{b}{2}\right)^2 + d^2}^n = \frac{1}{d^{2n-1}} \int \frac{du}{(u^2 + 1)^n}.$$

- If  $n = 1$ , then

$$\int \frac{dx}{\left(x + \frac{b}{2}\right)^2 + d^2} = \frac{1}{d} \int \frac{du}{(u^2 + 1)} = \frac{1}{d} \arctan\left(\frac{x}{d} + \frac{b}{2d}\right) + C$$

- If  $n > 1$ , let  $\theta = \arctan(u)$ . Then,  $d\theta = \frac{du}{1 + u^2}$  and

$$\int \frac{du}{(u^2 + 1)^n} = \int \frac{d\theta}{(1 + \tan^2(\theta))^{n-1}} = \int \cos^{2n-2}(\theta) d\theta.$$

Alternatively, integrate by parts and find a recursive formula.
